THE UNIVERSITY SURGICAL CLINIC

ITS FUNCTIONS AND ORGANIZATION *

DEAN LEWIS, M.D.
BALTIMORE

Each generation has its own problems to solve. Not infrequently these are not new. Many are inherited from a previous generation or generations. Some have been partially solved; some have never been taken from the pigeonhole in which they have been conveniently placed.

The question which is being asked almost constantly these days is, What is the object of medical education? This question being answered by the doctor or educator most vitally interested, he usually proposes some system of education which is guaranteed to remedy all the defects and to lead rapidly to the establishment of the ideal. At present there is no need to enumerate the panaceas which have been suggested which, if taken, would place the recent graduate in his proper relation to the patient, to investigation, to industry and to the rural communities which, if they do not organize in self defense, are apt to have forced on them a mediocre profession by some of our most practical medical educators.

Each succeeding generation should start higher in the scale of knowledge than the preceding one. If the recent graduate were to be content with the knowledge of the preclinical branches that most of us have after several years of what may be designated as fairly successful clinical work, the level of the profession would sink rather than rise with each succeeding generation.

The object of a medical education is to enable the student to attain the highest level of knowledge in the field of medicine and its subsidiary branches attainable for him within the limits of time which may be given to the subject, when provided with the needed and best attainable physical equipment. The faculty should arrange the student's time and the sequence of subjects taught, and the lay boards of universities and hospitals should supply the necessary equipment running smoothly so that this educational system may go on indefinitely without jars and an ever increasing efficiency in productive scholarship. The most intimate relationship is thus established between trustee, teacher and student. Judging from the literature which has accumulated on medical education during the last sixty or seventy years, I believe that we are justified in stating that the progress has been slow. High points have been reached; then the wave has receded to a dead level. We are still looking for the ideal curriculum, discussing the elective system; academic freedom; the type of professor required; the method of his appointment; the character of examination given by state and national boards; whether the part or full time system is best, and whether the clinical studies should be carried on in preclinical years.

The following statement, made about fifty years ago, seems essentially modern:

> If I am not mistaken, our medical faculties are just now generally inclined to give greater weight to academic work; hence the cries of the Philistines to the effect that practical sound training of the physician is being neglected and that too much weight is placed on scholarship. Even if this be granted in certain respects, and it is true that definite methods of instruction have not been found for much of the new content given to the natural sciences through the investigations of the last decade, I can see in it no great misfortune or any reason for threatening to change the character of our universities. It would surely have been much more regrettable if other nations had surpassed us in scientific research while we clung to cast iron forms.

This statement seems quite modern and up to date. The seeming desire or so-called need of making all medical education practical is discussed ad libitum today. There can be little argument—scientific education is the most practical; for practice must be based on facts revealed by science, and the scientifically prepared physician will be able to render to the sick in his community a service, not necessarily a sympathy, which is dependent largely on the character of the man, the value of which cannot be measured.

The present day tendency to place clinical subjects in preclinical years seems to me to be bad. There should be no need of making concessions in order to interest the student in preclinical subjects which form the foundations of the clinical branches, if they are properly presented.

The student acquires the sense of scientific training only in his student days. A developing scientific spirit is often completely killed by the early development of medical routine. The importance of an early scientific medical training cannot be overemphasized. The interest developing from a spirit of investigation or close thinking often determines the student's intellectual level for the remainder of his life.

DEFECTS IN MEDICAL EDUCATION

There are defects in any system. These, perhaps, are not due so much to the system as to human nature, and there is a good deal of human nature in all of us. I have been associated with medical students for a

---

* Delivered at a dinner given Dr. Lewis, Jan. 22, 1926, by the surgical staff of Johns Hopkins University Medical Department, alumni and friends.

number of years as a teacher of anatomy and surgery, and from time to time have been greatly discouraged and disappointed because principles were not known, facts forgotten and the relative values of different clinical phenomena unappreciated. We are inclined to think that the student should be as familiar with these things as we are, and disregard the fact that twenty years should permit one to accumulate many facts, if we are endowed with only an ordinary mental equipment. The teacher should place himself in the student's position, rather than place the student in his. A regard for the relative position of the two as to time and experience is hard to maintain.

The two great defects in medical education at the present time are the failure to bridge the gap between the preclinical and the clinical years and to correlate clinical and pathologic findings, thus giving the picture of disease as a whole. Preclinical teachers are often severely criticized because of what is regarded as poor preparation of students when they reach the clinical years. Each preclinical subject is a science in itself and should be so taught; but from time to time the application of the science to the clinic might be taught to advantage. The teachers are often separated and have no opportunity or even make no effort to know the problems which they have in common and which might easily be solved by free discussion. It is as much the function of the clinical teacher to carry on some of this instruction through the clinical years as it is the function of the preclinical teacher to initiate it. It would be an excellent idea for the anatomist and surgeon, the pathologist and the professor of medicine, the pharmacologist and the professor of therapeutics and medicine to meet groups of students or the entire class during the last quarter or trimester of the second year and discuss freely the scientific phases of their work and the application of principles learned to disease and injury. It is much more important that the teachers know and understand one another's points of view, problems and methods than that clinical work be begun early in the medical curriculum.

Medical teaching is disconnected. It is rare for a student to observe disease throughout its entire course or treat an injury from its inception to recovery, when the patient can be returned to the work in which he was originally engaged. He may observe the gross clinical picture at one time, the gross pathologic picture at any other, and the microscopic at still another. These may even be demonstrated in other departments. Too frequently the whole picture is not presented and impressions which should be correlated are disconnected. But rarely with a small material, for example, is a student able to follow a fracture throughout its entire course, to note the indications for a change of fixation or traction apparatus, to study the progress by roentgen-ray examination and to follow the nerve and muscle injuries which are not infrequently associated with the fracture. This sometimes is due to a low bed capacity, and the turnover must be rapid in order to provide a diversity of clinical material. The argument is frequently made that a large material is not necessary, because diagnosis is taught in other departments, and that repetition is not necessary. Clinical knowledge is based on accurate observation. Variation in the clinical picture must be recognized if a clinician is to be developed, and repetition may become the basis of knowledge.

During the last few years, there has been a tendency to minimize the importance of clinical medicine and surgery. While a firm believer in the laboratory and its place in the general scheme of medical education and practice, I believe that the importance of the laboratory has been overemphasized. During a reform there is always a tendency for the pendulum to swing too far. We are not as keen observers or reasoners as the practitioners of the preceding generations. History taking is neglected, and the five senses are atrophied or rapidly becoming so from disuse or insufficient use. It is so much simpler now to make roentgen-ray examinations in case of a suspected fracture than to study deformities, determine the point of tenderness and make accurate measurements, that the old well known signs and symptoms of fracture and dislocations are hardly known. Clinical methods must be emphasized and taught, with the distinct understanding that laboratory findings will be used as supplementary facts to aid in the solution of the problem. The tendency to return to a sane, well developed scheme, in which the patient is still in the center of the picture from which the clinician cannot divorce himself, is rapidly developing. The percentage of error in diagnosis is undoubtedly much higher in that so-called clinician who relies largely on laboratory data as a diagnostic method than in the clinician who deals primarily with the patient and uses laboratory findings as needed and in their proper place. The test of the system is the highest percentage of correct conclusions.

Sometime in his course the student should do intensive work in some subject. He should be thorough, for if he does thorough work in one subject he has laid the foundation for a career which will be satisfying. He will have a hobby which he may ride.

During the last few years, the medical curriculum has been changed from time to time; many different instructional methods have been devised, and it has at times seemed to me that an almost continuous experimental program has been tried out on the medical student. Freedom in a curriculum is absolutely necessary and equally so is discipline. Ability and talents are not hampered or stifled in their development by strict discipline, if opportunity is afforded for scientific and advanced clinical work after the prescribed course is completed. It has been wisely said that no amount of discipline will transform slack, lazy, stupid students into energetic, industrious, intelligent doctors. If discipline will not work this startling transformation, it is more than certain that the spoon feeding of many of the ideal or standard curriculums will not make a hardy, self reliant, independent, thoughtful practitioner out of a fat, pasty, rickety student.

RESEARCH

Some of the students, stimulated by contact with a suggestive teacher or because endowed with imagination or curiosity, will attempt investigation. Not infrequently, I am amazed at the conviction of some of those in authority that students with investigative ability can be selected with certainty and ease. Many who discuss this most glibly are entirely lacking in this ability themselves, and would never strike a spark of imagination in any with whom they come in contact. Christian, in an address made at Chicago recently, emphasizes the difficulty of selecting students with investigative ability, and states that some schools taking only a few students have not justified the claims made in their selection.

Investigators are born, not made, and their true worth is often unrecognized by those of their own generation. Disagreeing with those in authority and running counter to tradition, they not infrequently encounter difficulties.

Investigation must be carried on. Vocal research is to be discouraged, especially that type which is so anxious to see that the other man should have the opportunity. Research is fostered by precept rather than by preachment. What is research? It has been described as a frame or attitude of mind. Medical research is the by-product of medical education. Unless a student comes in contact early with a man with an investigative turn of mind, he will not be inspired to search for the new and unknown, or even become familiar with the methods employed.

Billroth has defined research as well as any one I know. His definition justifies the smallest effort. He states that there are questions to which there are no intuitive answers. Observation must be deepened to scientific research, and that means long, hard work. Nature yields her secrets only in return for arduous labor. The method of research, of positing the question and answering the question posited is invariably the same whether we have before us a blooming rose, a diseased grape vine, a shining beetle, the spleen of a leopard, a bird's feather, the intestines of a pig, the brain of a poet or philosopher, a sick poodle, an hysterical princess, or a fractured femur. The most essential task of the study of science is precisely to convince the student of this and to familiarize him with it.

There is apt to be a lack of sympathy between the preclinical teacher and the clinician. Frequently, they do not have a proper appreciation of the character and value of each other's work. When teaching anatomy, I have not infrequently heard the clinician who attempted to analyze critically 100 cases of gallstones or 100 cases of duodenal ulcer, in order to determine accurately the symptoms, chemical changes in the gastric juice, indications for operation, and prognosis, spoken of rather derisively, and later, as a surgeon, I have seen a half pitying smile cross the clinician's face when vital staining of the islands of Langerhans was discussed. The attitude of mind with which the problem is approached is the important thing. Hasty publication should be discouraged. The man must be judged by the work which stands the test of analytic controls, rather than by the amount which is put out. It is unfortunate that from time to time appointments are made on research, in which the problem is suggested to the man, the method of attack determined, and the results put together by the director of a department. The early sterility of men who supposedly made brilliant beginnings is thus readily understood. Investigation should be independent. The problem may be suggested by another; the line of the attack and the solution of the problem should be determined and made independently.

Research is to be cultivated and the attitude of mind commended, even if the results are small. But few revolutionize the subject in which they are working and many contribute small beginnings which, accumulating, hasten the solution of the great problem.

INFLUENCE OF PERSONALITY

Teaching and the encouragement of research are two of the functions of a surgical department, the establishment of a school of surgeons the third. It has fallen to the lot of but few surgeons so to influence a group of young men that they have contributed to the science and teaching of surgery and have in turn developed a group to carry on the work. It is difficult, almost impossible, to determine the qualities which enable a man to do this. He must have the ability to recognize unusual talents in young men; must be unselfish, giving the brilliant student full opportunity and credit for his work, and must be willing to delegate to men in his department responsibilities in organization and teaching. Founders of schools differ widely in personality, but they have one thing in common. They attract men from far and near. Sometimes regarded as visionary, frequently highly imaginative, they impart to those about them an irresistible urge to seek knowledge for its own sake. The influence of such men is best indicated by a tribute paid by Johannes Müller to Rudolphi. It is as follows:

> Rudolphi was no less great as a man than as a scholar. Any one who knew him was bound to love and respect him, even though his frankness of speech might sometimes hurt a little; one could not long resist his charm. What above everything else he demanded of people was righteousness, honesty of mind and freedom from all unworthy motives. When he found these qualities he gave of himself without reserve, and never again allowed himself to be deceived by appearances. His real self finds expression in his poems, in which he often speaks of friendship. Whenever I recall his frank, cheerful, dignified features, his kindly seriousness, the energy and integrity of his character, I am deeply moved. In an ignoble mood I should avoid looking at the portrait of my fatherly counselor, and it is when I recall the noblest experiences of my life that I think at once of Rudolphi.

This is one of the finest tributes ever paid to a man. One must concede that it is the personal influence or the personality of a man that is the principal leaven in the development of a school. There are other contributing factors provided by the vision of the leaders. During the last fifty years few have equaled, none have surpassed, the German school of surgery. Langenbeck produced Esmarch, Billroth, and finally Kocher. The men to whom he gave the urge were placed in Germany, Austria, Holland, Serbia and Switzerland, and while only few knew him personally or were even in intimate relation with him, they were unconsciously influenced by his spirit and idealism handed down by other men.

ORGANIZATION

Besides personality, which is perhaps the most important, is organization. Early German surgery was distinctly influenced by the French school. Young German students journeyed to Paris to sit at the feet of Petit, Le Dran, Desault, Chopart, Dupuytren, Velpeau and Nelaton. For some reason the French school became less influential and stimulating, and the German school of surgery flourished. The spirit of teaching, investigation and cooperation which leads to the development of a school cannot be wooed with riches. Unexpectedly, often without any plausible explanation, she flees the favored spot and causes to burst into bloom sterile fields, out of which it has been steadfastly maintained that nothing good could come. She can be wooed only by arduous labor, self denial and idealism.

Organization is necessary in the development of a school. It has always seemed to me that in this country we have paid too much attention to the older men in the organization. The men in the surgical department who should have the greatest consideration and the fullest opportunity are the young men who, on graduation, show an inclination combined with ability for surgery, surgical investigation and teaching. A young man in a department should be relieved as largely as possible of routine operating and the routine care of patients, having at least half of his day free for work in the experimental surgical laboratory or in the laboratories of anatomy, physiology and pathology, to which he should have free and easy access. He should have ample opportunity to progress in the system, so that each year responsibilities commensurate with his development *may be given him. He should be paid a living* wage. Universities at the present time are in sharp competition with private clinics, which are able to pay higher salaries and not infrequently have a large material. In some of these clinics, the men never reach the position they desire. The system easily becomes blocked. There are several factors which militate against the development of any great number of schools in this country. Owing to certain defects in our educational system, men enter professional schools at a relatively late age and of necessity graduate late in life. The graduate should enter at an early age the school in which he develops, for the early productive years of his life should be devoted to the specialty which he selects. The salaries which are paid are not sufficient to keep younger men in the organization any length of time. Professional success in this country at the present time is usually measured by financial returns rather than scientific achievements. Many of these young men are not imbued with the idea that only the poor shall enter the Kingdom of Heaven, that the rich man is already damned for being rich, that poverty is in itself a virtue and riches in themselves a vice. The advancement of surgery could be greatly aided by the establishment of fellowships in the surgical department, each endowed for $50,000, which would give to the appointee a living wage and some money for books and equipment.

SURGICAL EQUIPMENT

Teaching of surgery, stimulation of investigation, and the founding of a school of surgery should be the ambition of a surgical department. What is required in the *way of surgical equipment?*

It has been stated that fifty surgical beds with a large outpatient department should be sufficient, if the classes are limited to sixty. This statement was made fifty years ago and has been repeated from time to time since. It no longer holds good. The specialties have developed at an enormous rate. Neurosurgery, urology, otolaryngology, plastic, rectal and thoracic surgery, all require beds. Gallstones, ulcers of the stomach and duodenum and hypophysial and thyroid disorders now receive surgical consideration. *Industrial surgery must also be recognized, for notwithstanding* the safety devices which have been introduced, large numbers of persons are still injured and these must be returned to industry as quickly and with as little disability as possible. Even with 150 beds, which represents the minimum capacity, the turnover must be rapid to teach students disease and to permit them to observe throughout their courses disease and injuries.

The outpatient department is and will remain an exceedingly valuable aid in teaching. In 1924, practically all the teaching of fractures at Johns Hopkins was conducted in the outpatient department. The relation between the outpatient and inpatient departments must be extremely close. The liaison between the two must be perfect. This necessitates a reorganization or readjustment of most outpatient departments. I have the profoundest sympathy for the man in the outpatient department who year after year does the drudgery with little or no financial reward, frequently without promotion or preferment. The relation between the two departments should be so close that the man in the outpatient department keeps in touch with the patient after he enters the house; he should be notified of and witness the operation if such is performed, and have the patient returned to him after discharge from the *hospital. A certain number of the 150 beds should be* reserved for men in the outpatient department who have ideas and problems on which they want to work. Such an opportunity will stimulate teaching and raise to a much higher level instruction in the outpatient department, which is often killed by dull monotony.

The surgical clinic should be a unit capable of doing all its bacteriology, pathology, chemistry and special examinations. Such an organization conserves time and enables members of the staff to be in most intimate touch with the material. It is not infrequently stated that the surgeon is more or less of a mechanic. Perhaps this criticism is more or less justified at times. The grounds for such criticism should be removed. The surgeon should be a diagnostician, a pathologist and a bacteriologist, applying largely mechanical therapy. Every man on the staff should have a special training in pathology, and some time during his residence should serve a period in the laboratory, handling tissues and teaching students. This is a large order but is the ideal toward which every surgeon should strive. It is generally believed that a high wall is raised between ideals and reality, between art and handicraft—a wall whose foundations have been well laid but which crumbles bit by bit as soon as properly trained men with purpose and determination put it to the test.

While the unit organization is the one which we hope we may obtain, it should be understood that there should be the closest cooperation with the other departments. The welfare of the institution should always be uppermost, and the fate of an institution is settled when cooperation between departments ceases to exist. *An increased bed capacity is already needed.* We are losing cases because we have no beds. It is bad business medically to turn patients constantly to other hospitals, as it is bad business commercially to refer purchasers to other stores. A channel is worn. It may be difficult to reverse or divert the stream.

PRESENT TENDENCIES AND PROBLEMS

Certain things are proposed from time to time which embarrass or interfere with the plans of those who *have to do with the teaching of medical students.* The tendency of state boards of examiners at the present time is to require a fixed inelastic curriculum which necessitates spoon feeding by instructors. The student must have taken a certain number of hours in a subject before he can appear before the examining board. In some instances different associations of medical colleges have attempted to make an ideal curriculum with the introduction of a certain number of required hours in the different subjects. On numerous occasions, I have attended meetings in which the curriculum has been discussed, and I have often wondered what impression such a discussion would make on a prospective student or a student in the first years of medicine. Each teacher seems to think that his department is of prime importance, forming the foundation of medical education, a the main difficulty seems to be to find hours enough in the day or a reasonable number of years to satisfy each department. Attendance at such a meeting readily convinces me that we think in terms of departments rather than in terms of the institution.

Difficulties are now arising as to the type of internship that a recent graduate should serve. A man may take a year in medicine, then a year in surgery, or vice versa, or he may take a year in pathology and then a year in medicine or surgery. If a student is to go into surgery, a year can be spent to great advantage in either medicine or pathology, and a man looking forward to a career in surgery should always have such a preparation. Such an internship gives the man an opportunity to do one thing well. If the habit of doing a thing well is acquired, there is no need to worry. The ordinary rotation service tends to superficiality. In certain states in which a fifth or intern year is required before the candidate can appear before the examining board, a rotating intern service is required. This is the age of standardization. All are made to run in the same groove. Individuality is suppressed in a country which prides itself on a democratic form of government The system of medical education and licensure is probably the most autocratic in the world. There is a tendency to fabricate the medical student on the plans of a Ford. In discouraging some of these tendencies, the alumni of a school can exercise a corrective and lasting influence.

There has been much discussion concerning the so-called full-time system. I have accepted two such positions and must therefore believe in it. There are, however, some dangers in it which must be avoided, if it is to serve its purpose. Even its most ardent advocates admit that at the present time it would not be desirable to place the entire staff on this basis, even if money were available to do so. I have considered this plan carefully, and at one time was requested to make a budget, having this in view. The minimum budget for a surgical department in which the entire staff was on full time was $100,000, the income from $2,000,000. It would be difficult to secure such an endowment for a single department. More money would soon be required to keep the department at maximum efficiency. In addition, money would be required to maintain free beds for such a department. To justify such an expenditure there would have to be an enormous return in productive scholarship, and exceptional surgeons and teachers would have to be developed in relatively large numbers. The most serious difficulty with the system is the possibility that those engaged in it may become cloistered and sequestered, and that private material, which not infrequently is the best material for teaching and investigation, may be reduced in amount.

No medical department or institution can divorce itself from the community in which it is located, or from the practicing profession. From time to time any institution has to indicate that it is an integral part of the community. The medical school and hospital can do this better than any other part of the university. A man may make a great contribution to electrical science or physics by which all are greatly benefited, but medical care is something more personal. The physician and surgeon are relied on when things are blackest and genuine comfort needed. In no profession that I know of are the personal relations so close as between the family and physician. If I needed a surgeon, I would think that I was entitled to the best, and I would certainly lose my interest rapidly in any institution which made it impossible for me to have the services of that man. The surgeon must control his time, but he should give the impression that he is willing to render service when called on.

I have read, as probably all of you have, Cushing's remarkable book "The Life of Sir William Osler." One cannot help being struck by the interest that he maintained in people in his community, in the members of the medical profession with whom he liked so to associate, and in medical societies. These associations were of mutual benefit. He directed the profession along better lines. He furnished the driving power so often needed, and, in turn, these organizations kept him in contact with the best and stimulated him to increased endeavor. His full life speaks more than words for the necessity of many contacts. The busy man is apt to be the productive man.

If the full-time man does not see private patients, he will lose material which may prove most valuable for teaching and investigation. In many charity hospitals, the material, while large, may be limited to definite groups of cases. It has always seemed to me that there is a greater diversity of disease among private patients, many diseases, in fact, which the graduate will see on entering practice. These patients also give the most intelligent cooperation, and are therefore most satisfactory in the investigation of disease. It has been my experience that private patients rarely, if ever, refuse to be shown in a clinic or to a small group of students. The possibility of the reduction in this material or its possible complete elimination should be seriously considered. The loss of such material might interfere materially with the education of the physician.

In the New York *Herald Tribune* there recently appeared an editorial headed "Art as a Healing Art." The first sentence of the editorial was as follows:

> When the Virchow Hospital in Berlin was erected, some one had the wit to suggest as a legend to go over the entrance, In treating the patient do not forget that he is a man

---

Brewers' Yeast as Supplement to Deficient Diet.—In the course of an investigation on the influence of dietary deficiencies on experimental tuberculosis in the albino rat, it was noted by M. I. Smith and F. G. Hendrick that a diet composed of 40 per cent rolled oats (6 per cent protein) plus 10 per cent purified casein supplemented with fat soluble A and inorganic salts failed to produce normal growth, such as is obtained when the rat is maintained on a synthetic diet of from 16 to 18 per cent of purified casein supplemented with fat soluble A, inorganic salts, and vitamin B. The addition of from 5 to 6 per cent of dried brewers' yeast to the oat ration produced a normal growth curve, irrespective of whether the ration contained casein, gelatin or neither. It is clear, therefore, that dried brewers' yeast satisfactorily supplements the oat kernel. Though the oat kernel is known to contain liberal amounts of vitamin B, the possibility suggested itself that the level at which oats were fed might not furnish this vitamin in adequate amounts. To test this possibility, a quantity of dried brewers' yeast was autoclaved for six hours at 15 pounds pressure, which procedure completely destroyed its vitamin B content, and this material was fed to rats. The results demonstrate that autoclaving brewers' yeast, though destroying its vitamin B content, does not impair its efficacy in supplementing the oat deficiency. The oat kernel is therefore not deficient in vitamin B, but is deficient in some other factor, a factor that is present in brewers' yeast and withstands prolonged autoclaving. Evidence is advanced to show that a synthetic ration with casein as the sole source of protein must be supplemented with this unrecognized factor present in yeast, besides vitamin B, in order to make it adequate.—*Pub. Health Rep.* **41:**201 (Feb. 5) 1926

SAVING TIME IN THE MEDICAL SCHOOL *

RAY LYMAN WILBUR, M.D.
STANFORD UNIVERSITY, CALIF.

With the introduction into premedical and medical courses of those subjects requisite for a proper understanding of modern medicine, there has been a prolongation of the training period for the degree of Doctor of Medicine to a point that is approaching the upper limit of reasonable requirement.

As physics and chemistry were introduced into the premedical curriculum, and experimental physiology, laboratory bacteriology and practical pathology found their way into the day to day work of the medical school, the necessary clinical training was pushed forward. This, based on the traditional and ridiculous "four-system" of American education, meant four years of high school, four years of college, and four years of medical school. When additional training of a practical sort was added to this, the medical student before he actually met the problems of practice had passed out of the stage when it is easy to train his senses and his social accommodations.

The result of this carried to the extreme, as it has been in some of our institutions, was to develop practitioners who seemed (at least to many active practicing clinicians) comparatively ineffective and who required too much machinery for the practice of medicine.

With the two-year college requirement, four-year medical course and the one year of intern, there has been an approximation to a more reasonable period of time consumption. This has been viewed as somewhat at the expense of proper scientific and broad general training by many of those who have most carefully thought over the whole field of scientific education with medicine viewed as a portion of that field.

It has become, I think, quite clear to all that there is no possibility of making a pathologist, physiologist, anatomist, bacteriologist, biochemist and pharmacologist out of every prospective medical student, and that it is just as impossible to turn out a radiologist, urologist, rhinologist, laryngologist, otologist, orthopedist and pediatrician in the later clinical work in the medical school. It has become clear to most medical teachers that a careful selection is necessary in order to provide broad general training, sound scientific training and adequate clinical training during the period from the late teens through the early twenties in the development of physicians. Careful selection in the fundamental fields, together with the elimination of the specialties, will give sufficient training time to turn out a well rounded general practitioner, if that becomes the program of the American medical school. It seems to me, then, that the first thing is to choose the training of a general practitioner as the goal of the regular medical course, and then with great care to select the subjects that are requisite; and, second, to choose with even greater attention the methods of handling those subjects, the amount of time to be given to each of them, and to insist on practical clinical training during the period when this is most possible to the young physician.

To begin with, it is going to be necessary to eliminate so far as is possible many of the traditional absurdities of the medical curriculum, and also many of the methods, including an abnormal number of lectures, certain sequences in training, and that sort of thing. With proper coordination by the various instructors, there is no reason why there should be the endless repetition to which the present medical student is subjected, leading him to lack of interest and preventing many students from obtaining that concentration and thoroughness which will mean so much all through later life. We should strive particularly for such concentration and thoroughness, rather than assist in that diffusion and dissipation of energies which is inevitable with repetition. Why should the medical student be told the same thing a dozen times by as many instructors? Why not stop *teaching* him, and let him get most of his information for himself after one or two exposures? Less time in the lecture room and more time in the library, at the desk, at the bedside, and in the clinic, will lead to that self-training which sooner or later every practitioner must obtain. The lecture system, together with the antique examination plans now in general adoption, leads to periods of hectic work, physical and mental exhaustion, and unnecessarily long vacations.

A proper use of the calendar year with short vacations and a reasonable study list should give the medical student a life of only moderate strain, similar to that which he will experience afterward, and with better results in his training. The long summer vacation has no reasonable educational or physical excuse; there may be an economic necessity for it in the case of those students who need to assist themselves financially. The organization of the medical course on a four-quarter basis, leaving one month, say September, in the year free and with vacation periods of a week at Christmas and at Easter, it seems to me, is an ideal plan. In this way it is readily possible to do the present four-year course in three. This provides ample time for that acquaintance with the long list of terms which every medical student must know, and which is one of the most difficult problems of the student. A proper mixture of work in the outpatient clinic, laboratory, hospital and library can be so arranged that an adequate amount of training can be offered without difficulty. If an institution is so deeply embedded in its own traditional methods (as many seem to be) that it cannot free itself, it is possible for the summer vacation period to be used for clinical and laboratory assignment of one sort or another with proper credit, thus reducing calendar time consumption.

If the quarter system is used for both the college period and for the medical school, five calendar years should without difficulty give all the work that is now obtained in the two-year college course and the four-year medical course, together with a portion of the intern year. Under this system, students who need to support themselves can drop out for a quarter or more at any time, and return when their finances are rehabilitated. Graduation is possible at the end of any quarter, so that there is no needless loss in time. In other words, by these methods we can in a shorter period of time give to medical students just as good, if not better, training, with less speed, fewer spurts, less talk by the teachers, more study and self-training by the students, and with better care of the mind and body.

Is it not about time to break down the rigid honeycomb of old procedures, which is getting so thickened that we often have more wax than honey? Is it not about time to look at the training of the physician as a new problem to be achieved in new ways? If we can get some of the arteriosclerosis out of medical education we can produce better physicians in shorter time with the same facilities.

SELECTING A HOSPITAL FOR AN INTERNSHIP

HENRY A. CHRISTIAN, M.D.
BOSTON

In recent years there has been an increased insistence on an internship in a hospital, subsequent to the completion of the course in the medical school, as a prerequisite to the practice of medicine in any form. Some states have made this a requirement for admission to examination for registration for practice. Medical schools are coming to a very general recognition of the internship as part of the plan of education of the medical student, and whether they award their degree of doctor of medicine before or after the completion of the internship, the medical curriculum is planned on the assumption that the internship will be taken to round out the student's medical course, and that, without it, he will have had an incomplete preparation to begin the practice of medicine. In other words, the internship is recognized as having a definite educational value; to be satisfactory for the student who has just completed his medical curriculum, it must have such a value.

With this requirement in view, what ways and means has the senior student for the selection of a hospital internship satisfactory to his need? In the first place, it must be recognized that a hospital may be adequate for its work in the efficient care of its patients and yet be quite unsuited for an internship that is to complete the medical school education of the student. In other words, a hospital can perfectly well be a class A institution as a hospital for the care of patients and at the same time be about class D for an educational internship. This applies particularly to special hospitals. However, the converse is not true; no hospital classed below A as a hospital can be considered a satisfactory place for an internship. In other words, no hospital in which patients do not receive excellent professional and institutional service is acceptable for an internship. The educational internship should be limited to class A hospitals, using the classification of the American Medical Association as a basis of grouping; this serves as a reasonably satisfactory index of a satisfactory care of patients, but it must be recognized that classification as an A hospital in itself does not indicate that the hospital is satisfactory for an internship.

As it is the educational value of the hospital that is the important criterion to the prospective intern, certain general conditions must be fulfilled. In the hospital, the intern should expect to learn how to apply to the individual patient the more theoretical knowledge acquired in the medical school and by repetition, with methods of check as to accuracy, perfect himself in the methods of his profession, the methods of both diagnosis and treatment, along with the acquirement of that somewhat intangible but no less important art, which, for a better term, we may call the understanding of the human relationships of patients. There must be in the hospital patients in sufficient numbers to keep the intern occupied, and yet not so many that he has insufficient time to study each one with care. The diseases of the patients must be sufficiently varied to give the opportunity to apply a major portion of the usual methods of diagnosis and treatment. The apparatus, including an adequate laboratory equipment to carry out these methods, must be available for the use of the intern.

It is the general idea, rather than the detailed form, of the foregoing that is important. Deficiency in number of patients may be offset by other features. Excess of patients may be made less of a disadvantage by highly organized methods of handling them. In general terms, in a graded internship,[1] twenty-five beds under the care of one intern during his period of responsible charge of patients may be regarded as a minium and fifty as a maximum for the educational purposes of an internship, but it should be remembered that in mere numbers there is no desideratum of desirability, and under special circumstances either less or more may provide entirely adequate educational opportunity.

The range of diseases of patients needed is rather more difficult to express in any definite or numerical way. A general medical service of the size already indicated, to which patients are admitted so as to include those likely later to need surgical therapeutics, will furnish an adequate range of diseases. A surgical service in which all the usual procedures of diagnosis are carried out will provide this range equally well. Just how far there is need in such an internship for the special services, such as pediatrics or obstetrics, is a question of considerable debate at present. It seems to me that its proper answer must hinge on what is to be the future work of the medical student and what are the opportunities within the medical school for practical work in these several branches. On these factors depend the educational value of the mixed service. This service, which on theoretical grounds is desirable, at once becomes undesirable if the period in each division is too much shortened. It has seemed to me that an internship as short as twelve months probably is inadequate in time unless it is an unmixed service in medicine for the man proposing to go ahead with a special service, and that any form of mixed service should be eighteen months in length as a minimum and longer if it includes any of the very special services. It should be noted that these are minimal lengths of service and not expressions of length of an ideal service. However, let me reiterate that it is not the form and the length but the quality of the service that is the important requirement, and it would be unfortunate for regulating bodies to attempt to express as requirements minimal or maximal numbers of beds and numbers of months of service or types of service except in the most general terms; it would be still more unfortunate to say, for example, that a mixed service alone will provide the educational opportunity to be regarded as a required part of the training of the medical student.

Hospital equipment and laboratory facilities hardly need definition in this paper. As far as they are concerned, in general, any class A hospital providing the other things discussed may be regarded as entirely adequate for the purposes of an acceptable internship. It may be added, however, that the intern must be required to do for himself the ordinary laboratory procedures of diagnosis without being expected to do the more complicated ones, which he is entirely unlikely to carry out for himself in future years as part of his own practice of medicine.

The first paragraph of this paper ended with the idea that the internship, to be satisfactory, must have a definite educational value. Herein lies the crux of the situation; all else discussed up to this point is merely machinery to an end. For "a definite educational value" there must be instruction and guidance. The men of the staff are more important than the equipment of the hospital and the number and type of patients. They must be willing to instruct the interns; they must be willing to spend time in the hospital engaged with the interns in the study of patients; they must be well trained themselves, and they must know how to teach.

---

[1] In a graded internship, the intern rotates from one type of medical work to another. A frequent arrangement is for him to serve a certain number of months in clinical laboratory work, then as junior aiding the senior in charge of patients, and finally as senior. Consequently, in his period as senior in responsible charge of patients, each intern is aided by two other interns.

It is of these phases of hospital work that it is most difficult for the prospective intern to obtain information. The annual report of the hospital gives the number of beds, number of patients treated and the names of the staff members. Often the annual report gives, in the form of tables of diagnoses, an idea of the range and type of diseases encountered. If the prospective intern knows the names of the staff, the American Medical Directory will give him a little idea of the qualifications of each, such as school and date of graduation and membership in societies. This, however, is meager and may be misleading. As to time spent in the hospital by members of the staff and their teaching ability, a visit to the institution or a talk with present or recent interns will help.

Looking about for any other criteria, it has seemed to me that the number of necropsies obtained on patients dying in the hospital is perhaps the best single index of the professional efficiency of the hospital, of the amount of work devoted to the study of patients by members of the staff, of the eagerness of the staff to learn, and its teaching abilities. In my opinion the physician who has studied his patient conscientiously and has watched the progression of his disease from day to day, who has discussed the disease and its manifestations in the patient with his interns, and who is sincerely desirous of learning more of medicine is the physician who makes every effort to secure permission for necropsy in all fatal cases and is keenly interested in what is found. When such men make up the staff of any hospital necropsy permits are sought on all fatal cases and obtained on a goodly number; and hence the percentage of necropsies obtained in any hospital forms a very good index of the professional efficiency of the institution and the desirability of that hospital as a place of an internship.

In a statement published last year in the paper of the Phi Rho Sigma medical fraternity, I gave the advice that any general hospital having more than fifty deaths per annum, in which the necropsies were 25 per cent or more of the number of deaths, might be regarded as a desirable place for an internship. I now think that 100 deaths per annum is a better standard to adopt, as the smaller number of deaths would include many hospitals hardly large enough to provide thoroughly satisfactory internships. With this idea, I have arranged a number of general hospitals with 100 or more deaths a year in a series based on the percentage of necropsies to the number of deaths, the institution with the highest percentage being at the top and the one with the lowest at the bottom, as shown in the accompanying table. This list comprises the Mayo Clinic and the larger hospitals of Chicago (data for Chicago obtained through Dr. Irons from a report of the committee on necropsies in the hospitals of Chicago to the governors of the Institute of Medicine), Boston, New York, Philadelphia, and Baltimore (data for these cities obtained by letter from the individual hospitals). The data are not always of the same year, and the list is far from complete. In general the figures apply to all deaths in the hospital except such as are referred to the coroner or medicolegal examiner; medicolegal necropsies are not included. In most instances, deaths and necropsy percentage include both private and ward patients. This is the case for all hospitals having 25 per cent or more of permission necropsies, except Mount Sinai Hospital; there the assistant director states that they are unable to supply information in regard to private ward patients; letters from the other hospitals with more than 25 per cent of necropsies state that private patients are included in the figures given. Private patients are included in the statistics of all the Chicago hospitals except the Cook County Hospital. Allowing for possible variations in the method of gathering the figures from different hospitals, the table is still a reasonably fair grouping of the institutions on the basis of percentage of necropsies per annum, and I think it shows the value of this as an index of the quality of the work of the institutions, though of course there can be considerable difference of opinion as to the proper comparative ranking of individual institutions.

Percentage of Necropsies to Number of Deaths in General Hospitals with One Hundred or More Deaths a Year

* Percentage on which permission for necropsy was obtained.

† Private wards not included, as the hospital administration does not have information with regard to necropsies on private patients. Without these, the comparative ranking for this hospital probably is too high.

‡ Charity wards only.

While there may be exceptions as to hospitals with smaller percentage of necropsies, I know of no exceptions as to desirability when the percentage is 25 or higher, and in general the higher the percentage of necropsies, the more suitable is the hospital for an internship. In my judgment, the hospital that has few necropsies is a hospital in which the staff lacks many qualities that go to make up the best type of medical man; often the staff lacks the courage to have a showdown of its diagnostic ability, a form of cowardice hardly consistent with the highest ethics and a real desire for progress. Most important is the fact that, without necropsies, the physician in charge of the case fails to realize his diagnostic deficiencies; he probably has ceased to progress in his medical knowledge and may even have retrogressed. There can be no poorer leader and teacher than he who no longer recognizes his limitations.

In giving 25 per cent of fatal cases coming to necropsy as a criterion of desirability of a hospital for an internship, I believe a very serviceable criterion of efficiency has been set, and hospitals should strive to maintain this level as a means of valuable postgraduate education for their staff as well as for their interns. Why should not this standard be set by the American Medical Association as an additional criterion of acceptability for an internship?

It is not amiss, perhaps, to point out that in hospitals with numerous Jewish patients there is encountered constantly the excuse that the Jewish religion has tenets opposed to the necropsy; certainly, that has been our experience in Boston. In the *American Israelite* for Nov. 19, 1925, will be found a full discussion of this topic, based on a study of the Talmud and rabbinic opinion, which it would be well for all Jewish physicians to read. From this, it seems clear that there is no authority or tenet of the Jewish faith opposed to the necropsy. Yet in a list of twenty Jewish hospitals, in 1923, there were only five in which the percentage of necropsies obtained on Jewish patients exceeded 25 per cent of the deaths, and in seven there were no necropsies at all. An active campaign of education on the part of Jewish physicians among Jewish people would do much to correct this situation. In other sectarian hospitals conditions are very similar, and many nonsectarian hospitals are no better. If my criterion of desirability of a hospital for an internship should receive general acceptance by the senior students of the better medical schools of the land, these hospitals with few necropsies would soon find themselves having great difficulty in securing good interns. It would seem to me that, if hospitals with a poor record in regard to necropsies expect to attract high grade men as interns, they should make strenuous efforts to increase the number of necropsies obtained on patients dying within or soon after discharge from the hospital. I may add that whenever such an effort is made, a goodly number of necropsy permissions is the result.

Some hospitals pay interns a stipend of some form. This should arouse in the mind of the prospective intern a strong suspicion of the inadequacy in educational value of the internship. I do not mean by this that there is anything reprehensible in payments to an intern; but knowing as I do the efforts at economy required on the part of all hospitals, I know that they do not pay salaries for service obtainable without salary, and that payment of salary is an indication that they do not offer enough of educational value in their internship to attract interns, and so they must add a monetary attraction in order to get them. The student without means may be forced to take a salaried internship, but he should realize that he is probably getting one of a depreciated educational value. It has always seemed to me that the salaried hospital resident job should be taken by the man who has completed his medical curriculum, which today means the completion of a medical school course of study plus an internship. To me there seems no more occasion to pay a salary in an educational internship than to pay a salary to the medical student during his course in the medical school.

Perhaps many of my views will meet with disapproval. They are merely the opinions of one who is greatly interested in the hospital training of interns. If they stir up a discussion that will enhance the educational value of the internship in this country, they will have accomplished all that I can ask for them. Whether my suggestions prevail or not is of little importance, provided their intent is attained—a better internship available to every graduate from our medical schools.

MEDICAL EDUCATION AND MEDICAL SERVICE

SOME FURTHER FACTS AND CONSIDERATIONS

WILLIAM ALLEN PUSEY, M.D.
CHICAGO

I have presented in previous papers[1] a large amount of evidence of difficulty and breakdowns of medical service, especially in rural districts. Rural medical service, however, has not generally broken down and when attention is called to the actual shortage in some locations, and the impending shortage everywhere, it is often assumed that a sufficient answer is that there are plenty of doctors in the country. Assuming that this is true, the serious fact is that the rural doctors are disappearing.

THE AVERAGE AGE OF RURAL PHYSICIANS

The conclusive evidence of this is the high average age of rural physicians. Several men in various parts of the country have called attention to this fact in their respective states. Following this hint I have in the last six months undertaken to investigate the age of rural physicians throughout the United States. The investigation was conducted as follows:

I wrote to the secretary of each state medical society the following letter:

> I wish to send a request, asking the names and locations of all of the physicians in his county, to a representative physician, who would probably give me a careful answer, in each of several rural counties of your state.
>
> Would you do me the favor to give the names of ten to fifteen such men with their addresses in various counties of the state which would be fairly representative of conditions of rural medical service. For my purpose I regard counties that have no town above 5,000 as rural.

In states with few counties, a smaller number was asked for.

It should be noted that I asked for counties which would be fairly representative of conditions of rural medical service, not those where service was worst.

Also it should be noted that I have assumed as a standard of rural communities counties that have no town of more than 5,000 inhabitants, while the census standard of rural communities is one having a population of 2,500 or less.

I received replies from forty-one of the forty-eight secretaries. The forty-one states heard from are shown in the accompanying table.

---

[1] Pusey, W. A.: Medical Education and Medical Service, J. A. M. A. 84:281 (Jan. 24), 592 (Feb. 21) 1925.

I then addressed to the physicians in each state suggested by the state secretary a letter asking the names and locations of all the physicians in his county.

This letter was sent to 366 doctors in 366 counties in the United States, and replies were received from 283 counties in forty-one states (77.3 per cent).

My investigation thus covers 283 counties in forty-one states; i. e., 6.9 counties per state. Some states show a return from a few counties because they have few counties or few rural counties. Taken as a whole, I think one could hardly get a more accurate cross-section of medical service in average rural counties in the United States.

These returns from each county reporting were then checked with the latest directory of the American Medical Association. The age of each physician and the number of years he had been in practice were also determined from the directory. All of the statistical work was done by my secretary, Mr. J. Q. Gowland, an experienced statistician.

Total.........	283	...	398	100				
Average age....................................					52 yrs.			
Average time practicing..................................						26 yrs.		

It is fair to call attention to the fact that this information is at least a year old now and that all the figures of ages would practically be one year higher at the present time.

As far as possible, physicians who had retired from practice on account of age or other causes were omitted.

The table given herewith shows in detail the results of this investigation. The outstanding facts of it are as follows:

The average age of physicians in 283 rural counties in forty-one states in the United States is 52 years.

The average time in practice is twenty-six years.

In these 283 counties there are only 398 physicians who are graduates of the last ten years; i. e., 1.4 physicians to the county.

In 100 of these 283 counties (35 per cent), no graduate of the last ten years has gone into practice.

The significant broad facts are that in 283 representative rural counties all over the United States the average age is 52 years, and only 1.4 graduates of the last ten years have settled in each of these counties.

This, it may be confidently assumed, represents the age situation of the men who are furnishing the medical service to the rural population of the United States. The life expectancy of men of average health of 52 years is not much more than ten years (the life expectancy of selected insurance risks of 52 years is only 19.4 years). Certainly their average expectancy of service can hardly be ten years. This means that by 1935, if the present conditions are continued, there will be an utter breakdown of rural medical service.

The findings as respects graduates of the last ten years are *even more significant*. Of such graduates, 398 have settled in 283 counties. That is 1.4 to the county. If they should continue to go to these counties during the next ten years at the rate at which they have *gone during the last ten years, if none of them die* and none of them remove or discontinue practice, the total number of doctors in these counties will be 796, or 2.8 doctors to the county. There is now a total of 4,410 doctors in these 283 counties, or 15.5 per county.

Not a single doctor of the last ten years has gone into 100 of these counties. That means that 39 per cent of rural counties are facing a breakdown of medical service.

There will undoubtedly be an effort to minimize the significance of this high average age finding, but it cannot be successfully done. A large group of men averaging 52 years old is approaching the end of its usefulness. The findings cannot be minimized on the ground that they are not comprehensive. They are not figures based on a few unfavorable counties. Care was taken to select representative counties. They cover the entire United States and represent a study of the ages of 4,410 rural physicians. No more can the findings in regard to graduates of the last ten years, in these districts, be minimized. One and four-tenths doctors for each of 283 counties in forty-one states is a record of failure to supply adequate rural medical service.

The evidence brought out in this investigation is exactly in line with that brought out in my previous investigations, with that of the Committee on Medical Service of the Conference of State and Provincial Health Authorities, in 1923, to which I referred in detail in my previous papers, and with the other evidence which has been produced by many other students of the subject.

All of this evidence leaves cold *most of those who* are interested *in medical education* as such. They repeat in one form or another the statements that it is social and economic conditions that will have to be changed; that new arrangements will have to be made to supply many places with doctors—actually meaning, with the sort of doctors we are now *producing*—ignoring the fact that these same places formerly were able to have doctors.

OUR SUGGESTIONS FOR RELIEF

More and more we are suggesting state medicine or the socialization of medicine in one form or another as the solution of the difficulties. This is the suggestion of Mayer and Harrison of the General Education Board. Dr. E. P. Lyons, dean of the medical department of the University of Minnesota, at the Conference on Medical Education, 1925, said in substance, "Suppose we do get socialization of medicine, what of it? I am a state employee and I find that status satisfactory." One of the great objections to socialism is that employees find the status satisfactory. The socialization of medicine would mean that the medical profession would be in the position of the public school teachers.

Our policy is also recognized in many quarters as leading to the disappearance of the general practitioner. Sometimes his disappearance is advocated. Dr. James B. Herrick recently has taken the position that the general practitioner is to disappear and should disappear.

The vague hope that quiets most men who are concerned about the situation is that we are actually producing enough doctors and perhaps some day they will be crowded out of the cities and specialties into practice where they are needed. Even if we are producing enough doctors, I believe that consideration will show—as I have attempted to show—that the crowding-out theory will not be effective in helping distribution to any practical extent.

ARE WE PRODUCING ENOUGH DOCTORS?

But are we producing enough doctors to hope for any action from this crowding out theory? Until recently I have accepted the contention as correct that we were producing all the doctors that were needed, that the difficulty was one of distribution. Recently doubts on this point have arisen in my mind. Particularly facts called to my attention by F. C. Waite, professor of histology and embryology at Western Reserve University have raised this question. The chief disconcerting fact which has come to my attention arises from an analysis of the Ohio situation, on the basis of Professor Waite's study of it.

After surveying the needs of the Cleveland district—that is, the district within 100 miles of Cleveland—Professor Waite estimates that that district will need 222 physicians annually to maintain the present ratio of physicians to population, without making any allowance for retirement before death. The present ratio of physicians to population in this area is 1 to 700+.[2] Western Reserve is graduating annually less than forty physicians. About 72 per cent of these, say thirty men, settle in the Cleveland district. That is, Western Reserve is furnishing the Cleveland district thirty physicians annually, when the annual needs of the district are 222 physicians. Where are the 190 to come from? Ohio has two other class A schools, one in Columbus and one in Cincinnati. These graduated, in 1925, 154 men. It also has a class B school in Cincinnati, an eclectic school, which graduated thirty-eight. Including these eclectic class B graduates, the total number of graduates, except those of Western Reserve, which we have already provided for in this estimate, amounted to 192. That is, if Professor Waite's estimate is correct, the Ohio schools are now graduating just enough men, including sectarian graduates, to take care of the Cleveland district! That district contains 51 per cent of the population of the state, and 38.43 per cent of the total area. If this estimate is correct, the Ohio schools then are graduating from all of their schools only half the number of physicians that the state needs annually. If all of the graduates of the state went to this Cleveland area, it would only take care of its needs, and leave 48 per cent of the population and 61 per cent of the area of the state unprovided for.

THE ACTUAL NUMBER OF PRODUCING SCHOOLS

I would call attention to the fact that the actual number of producing schools is less than a casual reader is apt to discover. The schools have been reduced from 160 to eighty, but of these eighty schools we have only seventy that are producing physicians. Ten of the eighty are class B schools; that leaves only seventy schools that we regard as satisfactory. But of these, and this is the pertinent fact new to me, ten of them—all class A schools—conduct only the first two years of instruction. (Next year this number will be reduced to nine.) They are only part medical schools and they do not produce a single graduate. In other words, from 160 medical schools we are now reduced to seventy producing medical schools of all sorts—44 per cent of our former number—and only sixty class A producing schools.

Also the number of students which these schools will take has been often sharply restricted to far below their former number.

When one considers this fact and remembers that we have only 44 per cent of the producing schools that we had twenty years ago, with a population of 115 millions against about 85 millions then, he finds explanation for the inadequacy of the medical schools of the country to take care of their applicants.

And yet Ohio is one of the richest and most prosperous states and one of the best supplied with medical schools. It has four medical schools, three of them outstanding schools. There are only five other states that have as many as four (Illinois, five; Massachusetts, five; Missouri, six; New York, nine; Pennsylvania, six). To meet the needs of the United States, the Ohio schools should not only be supplying all of the doctors necessary for the state, but a very considerable surplus for those states which have inadequate resources in medical education, and particularly for those twenty states which have no medical schools and which must look to outside medical schools to supply all of their physicians. The Ohio situation distinctly raises the serious question whether we are actually, as we confidently assume, producing the necessary number of graduates to supply the needs of the United States.

Also, the report of May 11, 1925, of the Committee to Visit the Medical School to the Board of Overseers of Harvard College seems to sense the same situation in New England, for it says: "It has been estimated that at least 200 young practicing physicians should come each year from the leading medical educational center of New England to supply the annual loss of doctors in this part of the country. It does not appear that the Harvard medical school is furnishing its full share of the needed quota."

THE FAILURE OF SCHOOLS TO TAKE CARE OF APPLICANTS

The Council on Medical Education and Hospitals indicates that this demand is more apparent than real, on the ground that many students make applications to several schools. It further shows that the present schools have a potential capacity of 5,000 more students than their present scheduled capacity, although why the schools do not utilize this potential capacity I have not seen explained. It further emphasizes that last year, for example, there were actually 1,500 less students in the class A schools than might have been accommodated. The fact that 1,500 more students could have been accommodated, if they had known where to go and had gotten there in time, does not cover the situation. Vacancies are not discovered until too late for prospective students to avail themselves of them. Further, it presumes a freedom of movement on the part of medical students which only men in unusually prosperous conditions possess. A vacancy in a medical school in South Carolina or Texas may not help the situation for a boy in Maine or Oregon, particularly if he cannot learn of it until too late to go there.

---

[2] Population, 1920, 2,975,045; number of physicians, 1923, 4,176 (Waite's letter).

Information of the overwhelming number of applicants for admission to medical schools comes from all over the country, and an illuminating illustration of the situation was recited to me by an official of the American Medical Association, in September, 1925, who was called on, the day before, by a young man who appealed to him for aid in finding a satisfactory medical school to which he could gain admission. There was absolutely nothing wrong with the young man's case. He had credentials showing first class credits for all of the premedical course from a first class premedical school. His preliminary education lacked nothing. He had an overabundance of the best sort of credentials from his teachers and from others testifying to his ability and scholarship and his general fitness. In short, no one had raised, or could raise, any question as to his being able to meet the formal and the essential requirements for admission to medical school—and yet he presented to my informant, who examined them, thirty-eight letters from thirty-eight different medical schools to which he had applied for admission and given his credentials, each of which stated that it was full and could not take him! This young man could go anywhere to medical school and had a strong desire to study medicine. His mission was to get suggestions of other good medical schools to which he could apply for entrance. My informant was not able to tell him, and could only refer him to the secretary of the Council on Medical Education and Hospitals. The only information, I was informed, that the secretary of the Council on Medical Education and Hospitals was able to give him was that last year there were 1,500 vacancies after the schools got going. But the young man was left in complete uncertainty as to where he could find entrance.

Of course, one reason for this is that the schools are giving preference to men who present credentials above those that are required. A doctor of philosophy will get preference over a master of arts, a master of arts over a bachelor of science; so that a man who has the actual scheduled requirements has fourth or fifth chance. Sixty-two per cent of the graduates last year of the regular schools had college degrees.

It is no exaggeration to say that there is as much demand for admission to medical schools now as there is for admission to some fashionable school for rich girls or for season tickets for fashionable symphony orchestras. And, as Sir James MacKenzie[3] has said on this situation: "If, in any sphere of life, a few individuals [and he is talking about medical teachers] are set apart and given power over their fellows, it is but human that such a select body will seek to aggrandize their position at the expense of their fellows. . . . In medicine, the teachers have practically taken into their own hands the guidance of education and all the intellectual interests of the profession, and ordain the course a man must follow who wants to become a doctor." If, in the last sentence, for the word "teachers" we substitute "educators"—lay and medical —and a relatively small number of them—this statement of MacKenzie's applies exactly to the situation now in the United States.

DENIAL OF THE EFFECT OF HIGH COST IN RESTRICTING DISTRIBUTION

There is a widespread tendency among those interested in the status quo to deny the effect of the high cost of medical education on the distribution of physicians or in the expensiveness of medical service. It is generally accepted by others. That principle applies to every commodity. We can give concrete illustration of its perfectly obvious action even in education. For example: A survey of earnings of the Massachusetts Department of Labor makes the following estimates:

> A man with a grammar school education earns about $45,000 between the ages of 14 and 60.
>
> A high school graduate earns about $78,000, 51 per cent more, between the ages of 18 and 60.
>
> A college or technical school graduate earns about $150,000, 233 per cent more than the grammar school graduate and 92 per cent more than the high school graduate, between the ages of 22 and 60.

In other words, as these men increase the extent of their education—that is, its cost in time and money—they are able to increase the price which they ask and get for their services.

We cannot deny the great effect of cost of medical education in influencing the distribution of physicians or the cost of their service and maintain our standing as logical reasoners.

NECESSITY OF GETTING MEDICAL STUDENTS FROM THE COUNTRY

We are oblivious to social facts in trying to devise some plan to get our graduates *to go to* the country. That is impossible with city graduates. Our real problem is to devise a plan whereby we can get students to *come from* the country. They are the ones from whom the rural practitioner must be recruited. The country lawyer, the country teacher, the country banker and business man, as the country doctor, do not *go* from the cities; they *come* from the country. And unless we succeed in devising some exotic substitute which the country will accept, we shall have to devise some plan whereby the country doctor can be developed from the country boy.

May I stop long enough to say that I have no respect for the argument which is constantly bobbing up in one form or another that the educated physician cannot be content with country life, or, if honest, satisfied with the services that he can give his patients there. I am quite willing to admit that many people, who have become addicted to the accessories of city life, think the country is intolerable. I, however, do not believe that this condition of mind is an evidence either of superior intelligence or of uncompromising honesty of ideals. I have no respect whatever for the Broadway attitude toward the country which we are assuming in the medical profession. On the contrary, I think there is very little difference, on the whole, between Broadway and Main Street, except that on Broadway you can conceal your defects better. Ambitions that seek the larger urban careers are often no sounder and are no greater evidence of intelligence, or more successful in their fruition, than are those that accept the simpler and often more satisfactory rewards of rural life. Coming down to our own profession: the city physicians—the rank and file of them, whether specialists or not—do not have more satisfactory, more intellectual or better rewarded careers than do their country colleagues. These statements are not talking to the gallery, and they are not due to any fanciful glamour that I have about the country doctor. They are based on a considerable knowledge of country doctors and an intimate knowledge of the realities of life of city doctors. I should not here consume time with this but for the fact that a great deal of this sort of thing is being uttered, particularly about the intellectual barrenness of life in the country; and it has weight both in our councils and in its effect on our young men.

---

[3] Mackenzie, James: The Future of Medicine, p. 219.

The country physician can handle 80 or 90 per cent of his practice with self-respect; his city brother can do no more. And as for the intellectual barrenness of country practice, the resourcefulness that it calls for, the responsibilities that it demands, the problems that must be tackled, furnish to an intelligent man a sort of stimulation that is satisfying and that brings out the best that there is in him. What E. J. Swift says of nations may very well be said of individuals: "The best period of a people . . . is their years of struggle, struggle against nature and against human adversaries." But there is no use talking this to the ordinary city bred man, and there is no hope of getting the rural work done by the seven year college men, men that President Nicholas Murray Butler aptly calls "the country club type" that we are turning out. I do not say this in disparagement of them. I am simply emphasizing the fact that that sort of men will not do the world's work.

If we can produce doctors only under such a seven year course as we are now insisting on, well and good. If that is necessary, it must be done. But in doing this we must make up our minds, and not try to escape the fact, that, as a result of our policy, we must forego medical service for the people of the country of the sort that they have had heretofore. It cannot be given.

THE EUROPEANIZING OF MEDICAL SERVICE

Our present policy in medical education is directed to the Europeanizing of medical service. I picked up the *British Medical Journal* of Nov. 14, 1925, and my eye fell on a report of a recent conference in London on the place of the midwife in the maternity service. I find the first sentences in the opening of the discussion as follows: "Dr. J. S. Fairbairn in an opening paper urged that there need be no rivalry between the general practitioner and the midwife. Their functions were not competititve but complementary. *The sphere of the midwife was attendance upon normal labor, and that of the practitioner was the general supervision of the antenatal and postnatal conditions and attendance on difficult labor.*" [Italics mine, W. A. P.] · That is what we are heading for in medical service now. Obstetrics is a function of midwives, except in abnormal cases! On the one hand, we make labor a specialist's job and a hospital proposition for the fortunate; and, on the other, we are rapidly bringing about a situation—already widespread in this country—where for the rest of the mothers it shall go to midwives! And how useful will the practitioner finally become whose experience in obstetrics is confined to abnormal cases?

It is not best for the medical profession nor best for the people of this country that, barring the fortunate few, medical service for the common man should be turned over to midwives and to nurses, and to other substitutes for the doctor that we are advocating, all of whom have had flagrantly inadequate training in comparison with anything that I am advocating; and to cultists.

THE RELATIVE COMPETENCE OF AMERICAN PHYSICIANS

And I am more opposed to the Europeanizing of medical service because I believe the failure of individual European medical service for the ordinary sick is not compensated for by the superiority of skill in caring for them of European physicians. I think, as a matter of fact, that European physicians in their surgical and other therapeutic skill—and I am willing to add in professional or other ideals—do not exceed the corresponding men that we have produced. I have no smug feeling that American medicine should be content to indulge in self-approbation—we have been no better than we should be—but no more have I any respect for the feeling that it should look with unalloyed admiration on Europe. Particularly is this true when it comes to the department of caring for the sick. And in research: I am conscious of the extraordinary opportunity for the pursuit of medical research which developed in central Europe under the effective control of autocratic government; but even in leading the way in research of which it is constantly implied we must look to continental Europe for our models—even in leading the way our showing will bear fair comparison: Gorgas, Reed, Weir Mitchell, Leidy, Marion Sims, Morton, the dentist, produced under conditions of education worse than ours, Beaumont, McDowell—these are not names that suffer by comparison with any list of any country. I should be entirely content to see American medicine continue to develop along the lines of American genius.

QUALITY OF OUR STUDENTS

One of the assumptions that we make is that we are getting a better quality of medical students now than heretofore. That is probably a gratuitous assumption. In it we make the fundamental mistake of considering education the equivalent of intelligence. It is, of course, nothing of the sort. We are getting young men of more education, but this fact is offset by our limitation in choice to those of fortunate material position. We are excluding an immense number of boys of high intelligence and boys who are trained to effort, to responsibility, to self-denial and the overcoming of hardships and whose natural intellectual strength is better for this training. As a matter of fact, it is probable that the quality of medical students today is no better than it was formerly. For example: Dr. B. C. H. Harvey,[4] professor of anatomy at the University of Chicago, who is in a position to appraise the quality of students we are getting now, and who has been studying this question, says:

> Comparisons indicate that there has been improvement in the last ten years in the general and special knowledge which students bring to professional schools, but that there probably has been no increase in intellectual power and none in the character of the students.

---

[4] Harvey, B. C. H.: Science, June 21, 1924.

EFFECT OF THE EXPENSIVENESS OF MEDICAL EDUCATION ON THE SCHOOLS AND ON THE STUDENTS

In the problem we are considering, the question of the expense of medical education to the student is little more important than that of its expensiveness to the institution giving it. In the last twenty years, medical education has for the first time become the favorite of philanthropy and has had unlimited amounts of money placed at its disposal. This has been due in part to the influence of the great foundations—specifically the Rockefeller and the Carnegie foundations. With the institutions they have endowed as the examples, the rest, with the pressure we have been able to bring to bear on them, have had to follow suit or lose caste. I have no disposition to question the motives of these foundations —I have unfeigned admiration for them—but I think the question may fairly be raised whether their course has been an influence altogether for good in our policy of medical education.

The chief spokesman on medical education, first for the Carnegie Foundation and then for the Rockefeller Foundation, has been Mr. Abraham Flexner. Mr. Flexner's ideals in medical education are exemplified in Johns Hospkins Medical School and in the German universities, of which Johns Hopkins has been our nearest exemplar. And with the enormous funds which have been behind the policies that Mr. Flexner advocated—and with the good qualities of those policies—the policies of the foundations in medical education have become the policies of American medicine. The result is we have set up standards for medical schools which can be actually reached only by a few institutions. It is apparently the policy of the General Education Board to establish a few medical schools in strategic locations which shall exemplify its ideas of medical education. We need a few such institutions; but we need many more, not ineffective and often weak imitations of these, but less ambitious schools devoted to the sound preparation of physicians for the everyday work of medicine. One trouble is that every school wants to be high-brow. Nobody wants to do the ordinary useful service. We see the same human trait in practice. We had it well illustrated in the venereal and genito-urinary service in the army during the Great War. We had no trouble in getting men who wanted and were able to do major genito-urinary surgery—of which we had little to do—but nobody wanted to treat the common venereal infections; and we found it impossible to get enough willing competent men to do this vastly abundant and important work.

The report of the Committee to Visit the Harvard Medical School (1925) estimates that "the Harvard medical school takes annually from the community, including the yearly expenditures and the interest on the school plant, but excluding that of the adjacent hospitals, the amount of a million dollars." Harvard has approximately 500 students in its medical school. It is then costing Harvard approximately $2,000 a year to teach each medical student, or $8,000 to produce a graduate, if every student graduates.

Or take, again, the new Vanderbilt medical school: It represents in buildings and endowments over $8,000,000. This means in interest alone an overhead of $400,000 a year. Its capacity is 200 students.[5] That means that each student will cost the institution $2,000 a year for his education.

Bevan[6] estimates the cost of the development of a medical school plant at from $1,500,000 to $3,000,000, exclusive of 10 to 20 acres of land in a large city! His estimate of the annual cost of conducting a first class medical school is from $165,000 to $350,000, which he estimates to mean an endowment of $3,500,000 to $7,000,000, a total for buildings, exclusive of grounds, and for maintenance of from $4,800,000 to $10,000,000, "and this is without charging to the medical school the cost of building and maintaining hospitals and dispensaries, or conducting the clinical departments on the so-called full-time clinical basis."

This is making medical education prohibitive to educational institutions as well as to students.

It is costing society from $5,000 to $10,000 to produce each of its doctors, and the doctors an aqual amount more.

The General Education Board[7] assumes that a college needs $250 annually per student—i. e., the graduate costs $1,000; and less than 8 per cent of the students are in college thus circumstanced. Medicine is four or five times as expensive, and 100 per cent of the schools are supposed to have the necessary income for their proper support.

Of course the expensiveness of medical education now is chiefly due to some of the policies which we are urging or requiring. Among these are:

1. The emphasis on the importance of the full-time professor, usually in a very strict sense.
2. The emphasis on research rather than on teaching.
3. The selection of teachers on the basis of research rather than teaching.
4. The urging of the teaching and research hospital.

The responsibility for these lie largely with the foundations and with their small group of advisers in medical education. The foundations have not, I am sure, tried to force their influence on us. On the contrary, they have tried to avoid this very thing. Some of their chiefs have spoken against the danger of some of these policies, as, for example, the policy of undertaking to produce investigators rather than practitioners. Nevertheless, these policies have represented their attitude as expressed by their usual spokesmen and by the schools which they have chiefly endowed; and the weight of the foundations is so enormous, because of the potential endowments from them which expectant schools see, that the evidence of their preference for these policies has had more influence than the most insistent advocacy in other quarters could have exerted.

It is further true that many of the chief spokesmen on educational policies in our councils have not viewed the situation with a background of wide experience in the practice of medicine or, sometimes, even in teaching. This situation has been exaggerated by the full-time teachers. They are apt to speak purely from the academic standpoint. They are interested in medical education as such; its practical application in medicine may be a matter of small concern with them; sometimes actually of disdain. It is not true that they have not contributed valuably to medical education, but the danger of it is that these groups are more interested in education itself than in its product. Their ideal is the "university of applied biology," as the Harvard committee calls the Harvard Medical School.

CRITICISMS ON OUR EDUCATIONAL POLICY

All of these policies are not only open to criticism on account of their expensiveness, but to close scrutiny as to their pedagogical soundness.

The full-time professor policy is the object of widespread criticism, and I shall devote few words to it, beyond saying that I am skeptical about it. I should be willing not only to see the clinical work done by part-time men, but the fundamental work as well. We seem to be more sensitive in medicine about this than is science in general, for it is the constant experience to see professors in other fields than medicine actively engaged outside their academic positions. One of the most brilliant investigators in American science, the holder of a chair of pure science in one of our greatest universities, told me in recent years that there had never been a year since he held a professorship when he had not earned more than his university salary in business, plain ordinary business.

Research *and education are not the same thing.* Overemphasis on research is overloading medical education. The undergraduate student is not, except in very rare instances, prepared for research or likely to benefit by the attempt, and very often no more is the man, who may be an excellent teacher, suited for it. As James Harvey Robinson says, "The sustained and arduous scientific work which has gradually built up our fund of knowledge is a pursuit for the few." Research also is not the criterion on which to select undergraduate teachers. Teaching is a function calling for definite capacity, and investigators may have little of it.

J. B. S. Haldane,[8] reader in biologic chemistry at Cambridge, says on this point:

> A great discoverer can generally expound his own work, but he may be a thoroughly bad elementary lecturer and an extremely incompetent administrator of a laboratory. It would be an advantage to education as well as to research if these duties could be more often separated.

And, as Robinson [9] says again, "In the enterprise of rehumanizing knowledge it is necessary first to recognize that specialization, so essential in research, is putting us on the wrong track in education."

The upshot of it all is that in our worship of research we are not only making the expense of medical education prohibitive, but we are on the wrong track in undergraduate education.

Suppose we returned to the policy of education for its own ends—to the position where the students got this impression: "Your business here is to equip yourselves for the practice of medicine, on the basis of existing knowledge"; suppose, then, we picked our men carefully on the basis of fitness and quickly got rid of those who showed we had made a mistake in their selection; suppose, then, we gave them three academic years of nine months of sound education in two and one-half calendar years; and then suppose we put them in good apprenticeships in hospitals for at least eighteen months, where they would learn the practice of caring for the sick by actually doing it under experienced men. Can any one doubt that we would make well prepared doctors in that way? That is about the way nearly all the best physicians in this country have been educated. The question is whether we shall turn out well grounded, soundly trained physicians, or, for the most part, weak imitations of Ph.D.'s.

Such a course provides for adequate clinical training —the essential things of all others. The laboratory is all right, but the elementary laboratory training a student needs to become familiar with laboratory methods in science and with the simple technic he needs in practice is easy, compared with a clinical training; but it cannot be substituted for it. Sir James MacKenzie has considered this subject in the chapter on medical education in his book "The Future of Medicine," and has sharply criticized present American medical education on this score.

This is the great defect, constantly criticized by clinicians, in our present type of research graduates; they are dependent on the laboratory. They do not know clinical methods or appreciate their importance. That does not make independent, useful practitioners. The resourceful man has his equipment under his hat and in his hand, and he gets it, not in the laboratory, but in clinical experience.

Suggestions such as I am making have the approval of a very large part of the profession, including many of the ablest men in it, but the opponents of them think it is a sufficient answer to say the suggestions are to give a superficial and inferior education—poor doctors for poor people. The attitude of a good many is well characterized by Robinson [10] when he says, "Those professionally engaged in the business of education are wont, as Vablen puts it, to indulge themselves in 'truculent quietism.' This permits of free expression of discontent without threatening comfortable habits."

Charges of superficiality and unsoundness cannot be made to hold against such an education as I have outlined, provided it is sincerely and soundly carried out. A less extensive education, thoroughly well grounded, would be better than the excessive amount of detail we are trying to cram into four academic years; that is unsound education. Let me quote on this point some thinkers on education of the highest rank:

Sir James MacKenzie says:

> It is far better to understand a few matters thoroughly than to have a superficial knowledge of a great many things.

Professor Robinson,[11] who, let me remind you, is the author of the "Mind in the Making" and the "Humanizing of Knowledge," one of them certainly an epochal book, says again:

> It is amusing to note the many things which college instructors and writers of textbooks include in their lectures and manuals which they themselves would not be able to recollect between times.

And as that other great educator, E. J. Swift, professor of psychology and education in Washington University, puts it:

> In science, conclusions and principles should be remembered. They are few, and facts are many.[12]
>
> Information is of value only to the extent to which it enters into one's thinking.[13]
>
> It "from the standpoint of memory is of two kinds: That which we need so constantly that it must be kept 'in mind,' and that which we look up as occasion arizes. . . . Efficiency requires, among other things, that the mind be not overloaded." [14]

And take even the opinion of a man in a specialty so elaborate as Paul Ehrlich's, of whom it is said: "It is interesting to note that he considered the acquiring of unnecessary knowledge as actually undesirable."[15]

Let any one who doubts the soundness of the principles stated by these men consider not simply the knowledge which constitutes his daily working equipment, but that which forms the background of his intellectual position in life. I would reduce the time of academic *undergraduate medical education* on the basis of these sound educational principles. With such principles as a guide, and with insistence on a supplementary clinical training, I have the temerity to believe we could very much improve on the longer education we are now giving.

As to how I would reduce the length of the academic course in medicine I shall only hint by referring to my experience with this paper: It was originally twice its present length; when I was confronted by the necessity of shortening it, I did so—and to the advantage of the paper.

7 West Madison Street.

MEDICAL EDUCATION AND THE YALE ANNOUNCEMENT

CHARLES R. STOCKARD, Ph.D., M.D.
Professor of Anatomy, Cornell University Medical College
NEW YORK

We may ask regarding the medical curriculum the same old question which Professor Jennings[1] has recently asked about man, "What's the matter with the medical curriculum?" and no antiphonal chorus answers back, "It's all right." If it is not all right, what is the matter with it, and what has it failed to do? There is nothing more important to the student or to the medical profession than these two difficult questions.

A certain group of articles on medical education usually begin with the statement that the chief object of medical education is to produce capable practitioners of medicine. Such an assertion sweeps far beyond the border of obviousness. No sane person questions the statement or is unaware of the thought conveyed. The chief duty of the medical school *is* to educate or develop practitioners of medicine, but this obvious assertion immediately suggests the question, Who is to teach and train these future practitioners of medicine? Is not another major function of the medical school to produce the teachers and investigators who are to constitute the faculty of university medical colleges?

The problem in full involves two considerations: First, has the present system of medical curriculums in this country served excellently well for training the practitioner, and secondly, has it been successful in producing teachers for the medical faculty? Some might claim that the present system is very good, if not the best, for training the medical practitioner. However, an attentive listener will frequently hear from persons having considerable knowledge of the subject that this system does not give the best results with the materials at hand. Good physicians are produced, but it is also probably true that the system might readily be improved, so as to give a far better and more useful training to the future practitioner.

When we attempt to answer the second question, namely, whether the strict class system of the present curriculum supplies the teachers for the medical schools, all must admit that in many directions it has largely failed. The professors and teachers in the clinical subjects have chiefly, if not almost entirely, been trained under this system, but the best of these have invariably been obliged to resort to further individual training and education in order to equip themselves to start their teaching career. When, however, we consider the laboratory and so-called fundamental departments of the medical school, one is disappointed to find that the professors, teachers and investigators in these departments are not, in the majority of cases, products of the medical curriculum. A few years ago, I[2] pointed out that only three or four professors of biochemistry in American medical colleges had ever pursued the medical curriculum or taken a medical degree. About 50 per cent of the physiologists had been trained in other schools of the university rather than in the medical college, and only 55 per cent of the anatomists of professorial rank had experienced the training supplied by the medical curriculum.

This state of affairs certainly indicates a considerable lack of success on the part of the medical colleges in exciting interest in the laboratory branches of medicine, and also a failure to encourage and develop the type of student who is primarily interested in becoming a scientific investigator and teacher in the fundamental departments of the medical school. There is no doubt that persons with such interest do exist in this country, and that they go to the university to equip themselves for exactly this kind of a career. These persons, after attending the other schools of the university and acquiring their preparation, have then come to join the medical faculties of the country. They have been admitted through necessity, on account of the fact that the medical colleges have themselves been unable to produce a sufficient supply of teachers and investigators to man their own faculties.

The situation in some branches has recently bordered on the deplorable: A few years ago there was available at one time three of the most desirable professorships in this country in a given laboratory branch. But there was not, in the opinion of the faculties concerned, an altogether desirable man available for any one of the three positions—in fact, the condition demonstrated in a decided manner that there were not enough fully recognized professors to go around, even for the best medical schools. A considerable makeshift was resorted to in meeting this situation, and the general development of the particular subject in this country was at least not greatly advanced.

Recently, a strikingly similar situation has presented itself in another laboratory subject, and two of the leading medical schools with the largest budgets for the given departments in the country have been unable to secure the kind of men they most desire for their positions. In the laboratory departments of the medical colleges, there are often two or three positions available for every man well equipped in the subject. This is certainly a most embarrassing disadvantage to the medical schools and is quite in contrast to the situation in chemistry, physics and biology in this country, in which there is actually more than one fully qualified man available for every position in the better universities. If the universities do produce men scientifically trained and qualified to man the other natural sciences, why is it that the medical schools have not acquitted themselves equally well? This is certainly not impossible to accomplish in the medical school, as one readily recognizes on surveying the European situation. In more than one of the continental countries of Europe, there are several fully equipped men available for every vacant professorship in the medical sciences that occurs. Not only do these medical schools produce an abundant supply of men for their own faculties, but also it frequently happens that professorships in other departments of the university are filled by men trained in the medical colleges. In other words, the medical schools in several European countries are real functioning divisions of the university. These schools have not only trained practitioners of medicine which compared very favorably with our own medical corps during the Great War, but also have produced a distinguished personnel to man their medical faculties.

[2] Stockard, C. R.: The Laboratory Professor and the Medical Sciences in the United States, J. A. M. A. **74:** 229 (Jan. 24) 1920.

There are certain physicians in the country who would meet this problem by having these laboratory branches taught by practitioners of medicine on a part-time basis. They forget that teaching scientific subjects is a profession in itself and cannot be satisfactorily done as a side issue. The teaching of medical students is no more the job of an amateur than teaching chemistry to engineers. Surely one would not prefer an anatomist rather than an abdominal surgeon to remove his appendix any more than he would prefer a surgeon instead of an anatomist to explain the morphologic significance of structural arrangements. Medical education is now largely, as it should be, influenced by the universities, since they conduct most of the medical schools.

FAULTS OF CLASS SYSTEM AND TYPE OF CURRICULUM

When all is considered, there is some reflection on the total accomplishment of the American medical school in failing to produce the scientific members of the medical faculties, and the doubt also arises in the minds of many as to whether our schools really make the best practitioners of medicine out of the material that comes to them. One of the chief causes of this trouble is largely, I believe, the prevailing class system and the medical curriculum itself. The medical classes are run on lines closely similar to those of the elementary schools. The curriculum is, as a rule, much more rigid than even the undergraduate arts college curriculum. Many of the better medical schools have high requirements for admission, and their students must have received baccalaureate degrees from college. Such students are sufficiently mature and sufficiently educated to enter any of the graduate schools of the university; they are certainly advanced enough to be treated as individuals and to be allowed to work somewhat as their talents and temperaments direct. Yet in the medical school these college graduates are put into rigid classes, just as if they were entering an academy. Each class has mapped out for it a definite routine of courses which every member must attend at the same time and which the entire class must finally finish on the same day. A glance into the world at large would suggest to any one that no fifty persons can complete exactly the same task in exactly the same length of time, aside from the fact that they will not all do it equally well. Some persons are capable of completing a given task in half the time required by others while, on the other hand, some may require far more time than the average, and yet, in the end, the slow individual may accomplish the task best of all. Is it absolutely necessary that this class group of different students must lock-step through any particular course in the medical school? President Lowell[3] of Harvard has recently emphasized the fact that the individual student is the actual unit in education, not the course or the class. In medical education the course and the class may be actually smothering this unit.

Since there are to be only a certain number of courses and every student is to take each one of them, the members of the faculty naturally begin to compete and, to put it mildly, wrangle among themselves for their individual allotment of hours in which to attempt to cover their subjects in a routine way. This brings about a rigid and entirely arbitrary division of time for the several courses, which not only concerns a given school but has actually extended into national proportions, and committees are appointed from the country at large to determine how much of the student's time must be allotted to this, that and the other course.

In such an arrangement, it is erroneously presumed that all teachers can present one subject in a more or less satisfactory way in exactly the same number of days, and that any subject is equally important or equally unimportant, in spite of the ability and distinction of the teacher. One can scarcely imagine an arrangement more completely devised to suppress the individuality and taste of the student or more surely to stunt and dampen the originality and enthusiasm of the teacher. Periodic waves of dissatisfaction develop against this system and a national epidemic of curriculum revisions takes place, one of which we passed through only a few years ago. The interesting thing is that, in spite of this feeling of dissatisfaction, nothing really important happens to the curriculum; there is applied merely a process of addition and subtraction; a few courses are slightly extended in time and most courses are curtailed, but the general system of lock-step class performance is strictly maintained.

Now, is this type of medical curriculum actually necessary or essential in order to produce a good practitioner of medicine? Is it not possible or even highly probable that a better trained, more independent and thoughtful practitioner of medicine might be derived from a more encouraging and diversified type of education?

THE YALE PLAN

A highly promising and stimulating occurrence has recently been reported from the Yale University School of Medicine. The faculty there has decided to conduct the medical school in the same general way that has proved successful in the other divisions and schools of the university. Please let it be understood that by "university" I am not referring to the undergraduate college but to the schools that are attended by the mature students who have previously received their bachelor degrees from college. The graduate schools constitute the university in contrast to the college. The general attitude in the university is that a mature student enters there to receive an education or a training in some subject or profession that he desires to pursue throughout the rest of his life. He must be equipped for this job not merely by being crammed with facts but by being helped to learn the method and the philosophy of his calling. If, for example, he expects to be a chemist, he enters the school or department of chemistry and, in conference with one or more professors in that school, works out a general plan of study and then goes ahead on his own responsibility to attend certain courses of instruction and laboratory work, until he has finally covered the chosen field in a sufficiently complete way. He then applies for some form of qualifying test or examination, on the basis of which he is to be granted a degree and delivered into the world to work in his science or profession.

---

[3] 3. Lowell, Lawrence: Address before Meeting of American Medical Colleges, Boston, 1925.

The medical student, as I understand the plan, will approach the Yale medical faculty in the same way—he comes desiring to receive an education for the medical profession. He ascertains the general requisite of study necessary to attain his ambition and he also learns, of course, that the various subjects must be pursued in a more or less definite order because certain subjects presuppose a knowledge of others. The entering student will, therefore, probably register for courses in anatomy, chemistry and beginning physiology, but he will not become a member of a class. He may even be permitted to try certain clinical subjects before taking the laboratory branches, as Dr. Cushing[4] has recently suggested in a discussion of medical education. There will be no first-year class. There will merely be a school filled with medical *students*.

The department of anatomy will offer courses in anatomy that any one in the school may elect, and the professor will teach these courses in as systematic a manner as he thinks fit. He is free to make the course sufficiently long to cover the subject as he decides is necessary. If demonstrations are given, they will occur, of course, at particular times, and all students who care to attend them will necessarily appear at the given time. The laboratory work may also be systematic and formal or may be very open in its arrangement. The student is perfectly free to attend as much or as little of this subject as his interest dictates. The bright, fast student might be able to cover the subject in a very short period of time; the ordinary student would require longer, and the slow student, who might at the same time be a very intelligent person, could remain as long as he found it necessary to complete the subject to his own satisfaction. The professor's task is to encourage, stimulate and lead the students but in no sense to herd and to drive them in order to force them to study and learn the subject he is teaching. After the student has had a sufficient experience in a certain course, he then registers for further courses in the medical school, and is taken into pathology, medicine and surgery. The professors in these subjects, as in other branches of the university, will at their own discretion admit students to their course who they feel are properly qualified on account of their previous work and knowledge of underlying subjects. Examinations may be given at regular or irregular intervals, and all students having been previously registered in any particular course may present themselves for these examinations in order to qualify in the subject. Up to the present time, in all universities it seems necessary to have some type or method of examination in order to determine whether a student has actually succeeded in mastering a sufficient knowledge of a given subject; in other words, he must qualify on what he has undertaken. The world in general requires this much of us all.

The great advantage of the Yale plan is the emancipation of the student from the rigid class which holds back the quick, bright individual and embarrasses the intelligent, slow student, neither of whom keeps step with the mediocre pace-makers. The stupid person is readily eliminated, being unable to find his way without a herd to follow.

It is undoubtedly a most important occurrence for American medical education that the Yale medical school should have put itself on a truly university basis in its function as well as in its organization. The university method is certainly the one that develops individuality and originality in the student, and at present it is the only system that fully allows a student to become interested in certain phases of a subject and to be free to develop and follow his interest in those directions. The university system also encourages and promotes the highest and most stimulating type of teacher. The teacher must become a leader rather than a schoolmaster. The student becomes interested in the teacher and in his manner and methods of work, not as a person who is superior and set over him, but as a person of wider experience, with whom he is privileged to work as an associate. Every one remembers from his student days a few such teachers, and he values any opportunity he may have had to have been associated with them instead of having merely sat under them.

This step on the part of the Yale medical school will be looked on as quite a venture by a great number of medical educators in this country. It will likely be somewhat misunderstood. Some will sense a smack of radicalism. Others may imagine it the adoption of a loose, unsystematic, indefinite system which can never be substituted for the rigid arrangement now generally followed; but to all those who have worked and studied both in the college and under the medical curriculum drill, as well as in the true university system, there will appear nothing new or dangerous in this undertaking. It is just this truly university method that requires more of the student than any other—he is put on his own responsibility; he is treated as a man and an individual and, if he has the right quality in him, he always responds. The most earnest, sincere, hardworking group of students that one may find is to be seen working year after year in the university departments of biology and other sciences in this country. These students must stand on their own responsibility and their own initiative. Any person who thinks that the Yale medical school has lowered its standards or has made its medical course easier to get through had better try such a system for a year, and he will soon learn how much it requires.

Of course there is no reason to expect that other schools in the country may immediately adopt this change. Certainly not all of them could, nor are all students equally suited to such a method. But all medical schools that do inaugurate such a plan will very probably attract a highly qualified and intelligent group of medical students.

The country at large owes its thanks to the faculty of the Yale medical school for having taken a definite step in what is probably a very wise direction. It is at least gratifying that one school should have asserted its individuality and independence by introducing a really different system, rather than simply following through the stagnant style of addition and subtraction, as applied to the several courses in the medical college.

THE INCREASE IN MEDICAL KNOWLEDGE

Obtaining a medical education is, after all, an intellectual pursuit leading to one of the learned professions. Medicine is really a much higher profession than most medical men realize, and the fact that it may be practiced in a crude and routine way, with a kind of success and prosperity, does not argue against the fact that it can be properly practiced and possibly advanced only by persons understanding and applying scientific biologic knowledge. The curing of disease must be a reestablishment and adjustment of the deranged functions of particular organs and parts of the body, and in order to do this it seems logically true that the physician should have a thorough comprehension of the functions and interrelations of these organs and the way in which they have been disturbed or modified by the aggravating condition. This is certainly no simple problem, and in every sense is a most difficult one to undertake. It cannot be done on an arbitrary, dogmatic rule-of-thumb system which befits to some extent the trade school and leads to a trade or business rather than a profession. When one advocates poorer schools and short cuts and medical apprenticeships in order to produce cheap doctors to supply the country districts, we wonder and then realize that medicine has passed on considerably from where it was forty years ago. To become a constructing engineer today, with the vast developments in building and mechanics, one can scarcely qualify on the training that was adequate years ago. Yet, a trade apprentice may still become a carpenter or a mason. Medicine has advanced wonderfully and is a very different thing now from what it was at the middle of the last century. It may be stated that it almost requires a different taste and different type of mind for the highest quality of medical practice now as compared with then, and this is said with all regard and respect for the high ideals of the physicians of past generations. The ideals have not changed, and it is very questionable whether they have been improved on; but the knowledge necessary for an intelligent performance in the profession has certainly been remarkably revolutionized and increased.

Education in the fundamental principles of a profession is the kind of training which enables the professional man to attack and solve the problems that present themselves in practice. After all, when we really think seriously, we are inclined to believe that medical education does belong to the university system rather than to the academy drill.

Adequate Public Health Nursing.—It has been said that public health work today in any community can be measured by the extent to which public health nursing has been developed. To a certain extent this is probably true; but opinions as to what constitutes an adequate nursing service seem to differ rather widely. The theoretically effective ratio is usually 1 nurse to 2,000 or 3,000 population, and yet in ninety-nine large cities for which records are available the average ratio for the whole group is 1 to 5,000, approximately. It varies from 1 to 6,300 in the group of larger cities to 1 to 5,400 in the smaller cities. In the "ideal" plan of organization for a city of 100,000, proposed by the committee of the American Public Health Association in 1923, thirty nurses were considered necessary to provide adequate preventive work, or an increase to fifty nurses if bedside care on an hourly basis is provided. Even with more conservative provisions, it is apparent that the majority of cities at the present time are inadequately equipped to provide even a reasonably satisfactory service.—Cumming, Hugh: *Pub. Health Rep.* **41**:379 (Feb. 26) 1926.

PHYSICAL FITNESS IN THE COLLEGE *

WILLIAM R. P. EMERSON, M.D.
BOSTON

Perhaps there is no better demonstration of the fallacy that may arise from limiting oneself to a special point of view than appears in findings with reference to the physical condition of college men. The attitude of the physician toward health may too often be stated that as a result of the examination of an individual, if actual disease is not found, the individual is considered well.

By this process the human race consists of two groups—the sick who have been thus labeled because of medical examinations that look for disease, and all the rest who are perforce said to be well. During recent decades, this undistributed group has been somewhat reduced by discoveries that afford labels for previously unidentified diseases. Among these conspicuously appear thyroid disease, glycemia and allergy.

Work in college groups almost exclusively confined to medical examinations shows results on the whole very similar to those secured by Lee at Harvard, where actually recognized disease was found to be almost negligible from a statistical standpoint. This frequently means that, apart from some slight limitations placed on those with heart disease with reference to athletics, the college men are left to the tender mercies of the educator who feels justified in making the work schedule on the principle that all men are physically equal. The physical educator acts on the same assumption and often overtrains the physically unfit, not realizing their true condition.

If, however, college men are examined from a different point of view—that of impaired health or, as it may better be described, physical unfitness—a very different state of affairs is at once discovered. As Lee[1] says: "However, it was perfectly evident that although 95 per cent of the college population were organically sound, in that no organic defects could be found in any organ or tissue of the body, nevertheless 95 per cent of the college population were not entirely robust, healthy individuals." Thus, for example, 645 men entering Dartmouth College in the class of 1927 were distributed on the basis of the relationship of weight to height, as shown in table 1.

Table 1.—*Relationship of Weight to Height in Six Hundred and Forty-Five Dartmouth Students*

	Per Cent
Obese (20 per cent or more over average weight)	3
Safety-weight zone (0 to 20 per cent over average)	42
Borderline (underweight, less than 7 per cent)	25
Seriously underweight (more than 7 per cent)	30
	100

This classification, which is the result of a study of many thousands of physical-growth and social examinations made in clinics and schools, agrees in all essential details with the grouping used in a Carnegie Institution report made by Director Davenport.[2] Here it is shown that the underweight groups (characterized by Davenport as "slender" and "very slender") were from six to twelve times more in danger of tuberculosis and from three to six times more susceptible to respiratory diseases and nervous disturbances than the general population.

---

* Detailed accounts of the physical fitness work in colleges have appeared in the Dartmouth Alumni Magazine for February, May and November, 1925, and in the Massachusetts Institute of Technology Publications **60**, no. 11. Reports in more popular form can be found in the Woman's Home Companion for July and September, 1925. Reprints will be furnished on application.

[1] Lee, R. I.: Some Confessions of an Internist Regarding Body Mechanics, J. Bone & Joint Surg. **5**: 747 (Oct.) 1923.

[2] Davenport, C. B.: Report, Carnegie Institution, December, 1925.

If we make further examination of college men with reference to their health habits, we find that in this respect they are apparently no better off for having gone to college. More students who need to do so wear glasses at Harvard at the close of the course than at the beginning (freshmen, 38 per cent; seniors, 42 per cent). But in the matter of health habits a study of public, parochial and private secondary school students, and of men and women in their undergraduate years and in medical school, shows no indication of any increase in health intelligence, because training the intellect has little or no effect in improving health habits.[3]

Apparently this percentage of physical unfitness with the accompanying predisposition to disease, as shown by Davenport, is not being taken as a cause of alarm. Our early findings concerning children were very much the same, and these were abundantly confirmed by the draft during the late war. The published material from these draft board examinations gave a practical foundation for a system of preventive medicine, yet almost nothing has come from them.

We can do something more than comment on this condition of affairs, for we are able to report remarkable results in dealing with the situation as far as it concerns the college man.[4] We have hundreds of charts made in the early stages of work with children, which register the ineffectual results of the usual general attack on health habits and poor hygiene. Actual progress began when enough cases had been analyzed to make a rough classification of the real causes of the major part of these cases of physical unfitness. Attention was then focused on (1) finding the physical and social causes of the particular condition and accomplishing their removal, and (2) bringing together in an adequate program the forces necessary to raise the health intelligence of the individual. When the causes of the condition have been eliminated and he has become free to gain, nature and better habits of living will get the child well.

We have found, on the whole, that the same causes operate among college men as appear in dealing with the younger members of the growing period. College students naturally come from homes of greater opportunity than the average economic status. We have been surprised to find that there is often a higher percentage of underweight in the families of the well-to-do than in those who are socially less fortunate. The greater attention given by the former group to the removal of physical defects and to better food and health habits favored by superior environmental conditions seems to have been more than counterbalanced by the demands of a more complicated social life in home and in school, and by the overdoing of recreation and amusement.

Fully 90 per cent of these cases of physical unfitness can be traced to one or more of the following causes: (1) physical defects, especially nasopharyngeal obstructions; (2) lack of control (this includes many factors that are now receiving consideration in the field of mental hygiene); (3) overfatigue; (4) faulty food and food habits, and (5) faulty health habits. It is evident from a study of this group of causes that the condition they deal with is fundamentally medical yet that it is essentially a problem of education. This fact no doubt helps to an understanding of the slowness with which the situation has been brought to consciousness and dealt with by means of an adequate program.

Reference has already been made to the cordial support given by students and executives to this new departure in college health education. The only drawbacks were found among men of academic bias who cannot easily rid themselves of the class-room mind. To them the college program is a sacred matter not subject to change on the basis of new experience and needs that old conditions did not make it possible to recognize. Any interference with their vested rights seems unwarranted, and justification of the position taken, if any justification seems called for, is founded on formal and academic considerations and shows no appreciation of the dependence of mental development and achievement on adequate health conditions.

This type of mind is apt to be found as often among men working in the newer fields as it is among those who are closer to the classic tradition. In marked contrast is the remarkably wide vision of many of the men who are now at the head of large educational situations in school systems and colleges. They are able to see that, even for those who prize only such accomplishments as they desire to distinguish from the physical by emphasis on such terms as mental, intellectual and spiritual, the only sure road is that of essential health requirements. But these men of larger vision also see that they have responsibility for the great waste of life due to an effort to achieve academic, athletic and other results without making provision for the foundations on which they rest. It is the old story of bricks without straw; or, to change the figure, modern education demands and gets its pounds of flesh without considering that in so doing it renders impermanent and unserviceable much of the accomplishment for which it has worked so hard. After all has been taken into account, there is no more fundamental task for the school or college than to make such requirements as will bring its members at the start into condition to cope adequately with the factors essential to the training it is to afford them, so that during college life and in the years after leaving college they may pursue a course of mingled intellectual and physical activities in comfort and health, with a real appreciation of the joy of living and a sense of adequacy in meeting the economic and social needs of private and public life.

SUMMARY OF OBSERVATIONS

1. Of 645 men entering Dartmouth College in the fall of 1925, 3 per cent were obese (20 per cent or more above average weight); 25 per cent were underweight, but less than 7 per cent; 30 per cent were seriously underweight (7 per cent or more under average weight for height); 42 per cent were within the range of the safety weight zone.

2. The basis of comparison is the gain made by an average 16 year old boy—the last year of rapid gain—an annual rate of 8 pounds (3.6 Kg.).

---

[3] These findings on "health intelligence" will be reported in a later article.

[4] Practically all sections of the period of growth have been successfully tried out with this nutrition or physical fitness program, with the exception of the industrial group parallel in years with secondary school and college life. Preoccupation with school and college problems has prevented more than a glance at the possibilities of this section. Some experiments have been made by cooperating agencies. An interesting report is at hand from a group of nineteen young men and women ranging 20 years of age and more, employed in Indianapolis. The average percentage of underweight at the start was 18. During a term of thirteen weeks, the members of the class averaged 4¼ pounds (2 Kg.) gain in weight. This would amount to an annual rate of 18 pounds (8 Kg.).

In representative groups, the average gain per week for each member of physical fitness classes ranged from $^{36}/_{100}$ to $^{46}/_{100}$ pound.

A comparison of the weghts of 427 not including those in physical fitness classes, taken in the fall and in May, shows practically no gain in weight for the group as a whole, except that the obese group increased 50 per cent in numbers during the interval.

TABLE 2.—*Gains of Representative Groups (Basis of Comparison Gain Made by Average Sixteen Year Old Boy)*

	Men	Percentage of Gain	Average Pounds	Annual Rate, Pounds
	60*	295	...	24
	89	313	6.4	25
	70	267	4.7	21
	25	333	6.8	27
Athletes	21	464	6.2	41
Upper classmen........	22	476	5.7	42

* Averaged 12 per cent (18 $^9/_{10}$ pounds [8.6 Kg.]) underweight.

Eighty-nine men who were in physical fitness classes gained an average of twelve and one half times as much as did 427 men not in classes in a longer period of time.

Fifty underweight men in physical fitness classes gained four times as much as did fifty underweight men not in classes. The former group gained 150 per cent of the gain in height made by the latter group.

Twelve men in the first nine weeks of class work made 477 per cent of the gain they had made in the nine weeks before entering on the physical fitness program.

Ninety-one men reporting in April gained, by the time they entered college in September, 759½ pounds (344 Kg.). This amounts to 36 per cent of the actual deficit of the group reported.

Various groups in a physical fitness class averaging 333 per cent showed, in various sections, the percentages given in table 3.

TABLE 3.—*Data of Weight Gain in Various Sections of Physical Fitness Class*

Excess social activities...........................	267 per cent
Training for teams.................................	199 per cent
Physical overexertion	223 per cent
Not enough outdoors...............................	274 per cent
Sweets between meals..............................	216 per cent
Poor cooperation	216 per cent

In other classes, men observing late hours made nearly 100 per cent less than the group as a whole; tobacco users averaged 263 per cent, as against 307 per cent made by nonusers; those marked excellent or good for carrying out physical fitness program instructions gained from 50 to 100 per cent more than those marked fair or poor.

3. The underweight men average about six physical defects each—a range of from two to ten. About half of these were due to nasopharyngeal obstructions and about one fourth were defects of posture. From a third to a half the men had already been operated on for the removal of diseased adenoids and tonsils. In one group 84 per cent were recommended to have expert nose and throat examinations—48 per cent received negative reports and 36 per cent were advised to have throat operations.

In the class averaging 333 per cent in weight, the percentage of gain in the various groups was as shown in table 4. In the group averaging 295 per cent, those who deferred recommended operations averaged 152 per cent gain.

4. The chief difficulties, in the order of their effect on weight, were: (*a*) grouped examinations; (*b*) "chinning" season, carnival, and vacations; (*c*) competition in athletics and other extracurricular activities.

TABLE 4.—*Data of Weight Gain in Underweight Men*

Number of Physical Defects	Percentage of Gain
From 2 to 4..	378
From 5 to 7..	310
From 8 to 10..	153

5. For the entire freshman year of the class of 1927 at Dartmouth, the obese group showed the lowest percentage of illness from nasopharyngeal causes; the underweight students had twice as much nasopharyngeal illness as the optimal group. About 40 per cent of the students were absent for illness during the year, losing about five and one-third days for each man ill and about two days for the whole class.

TABLE 5.—*Morbidity Data for Class of 1927 at Dartmouth*

College Year	Percentage of Illness
1921...	29
1922...	29
1923...	44
1924...	32
Distribution According to Residence	**Percentage of Illness**
5 houses, each less than 50 men.........................	27
10 houses, 50 to 100 men................................	31
1 house, 103 men..	39
1 house, 155 men..	43
Residing in town...	56
Fraternities, 16 each....................................	32

6. The length of time for meals is given in table 6.

TABLE 6.—*Time Taken for Meals in Class of 1927 at Dartmouth*

Eighty Men	Average	Range
Breakfast	12.4 min.	7 to 19
Dinner	15.4 min.	8 to 22
Supper	16.0 min.	8 to 24

7. The average number of calories for twenty-four men was 3,000, with a range from 2,400 to 4,100. The seven men making the best gains and the seven making the poorest gains came within fifty calories of the average for the entire group.

8. In the class of 1928, at Dartmouth, the underweight men not in physical fitness classes who lost weight during the college year averaged 0.6 less in college marks than did those who gained in weight in this time.

For both semesters, the underweight men had twice as many grades of less than 1.0 as the average of all the members of the class, and three times as many as were found in the group ranging from average weight to 10 per cent above the average. In the attainment of grades from 2.5 up, the underweight men were below the average, and the safety weight group ran above the average.

The obese men, 20 per cent or more above average, ran below average in high college marks and above the average in low marks. They showed twice as many low marks and less than a third as many marks of the higher grade as were found in the safety weight group.

In a group of eight men "withdrawn" from college, seven deserved zero in "control" in the physical fitness classes. Their average "health intelligence quotient" was 43 on a scale of 100. Their average college grade was 0.8. Four of them were in the lowest decile group (10); two were in group 9; one was in 7, and one in 3.

In the class of 1927, in the Massachusetts Institute of Technology, a comparison of grades received in college during the first term and those given by the nutrition worker showed that the ten best in college work had been ranked in the physical fitness class an average of 68 per cent, while the ten lowest in college grades averaged 46 per cent in our class.

The highest seven in college grades made an average gain in weight of 359 per cent; the second seven averaged 299 per cent, and the lowest seven, 225 per cent.

LEAD POISONING IN NURSING INFANTS

REPORT OF TWO CASES DUE TO THE USE OF LEAD NIPPLE SHIELDS *

HERBERT B. WILCOX, M.D.
AND
JOHN P. CAFFEY, M.D.
NEW YORK

Lead poisoning in children is well known though not common. Lead poisoning in nursing infants is extremely rare. The previously reported sources of lead poisoning during the nursing age are varied. Congenital lead poisoning is rare. The two cases of Ganyaire [1] and of LeGrand and Winter [1] are undoubtedly authentic, as lead was demonstrated in the placental, hepatic and cerebral tissues of two infants dying in the first days of life. The excretion of lead in the breast milk of mothers poisoned by the use of lead-containing skin cosmetics and hair dyes was the source of lead poisoning in several young infants among the cases recorded by Dufour.[2] Suzuki and Kaneko [3] have recently reported that the long observed serous meningitis in Japanese infants is due to white lead powder used as a cosmetic by young Japanese mothers. One cannot be certain that the nursing infants may not also have sucked lead from the skin or hair of the mothers, or carried it to their mouths on their hands. Lead preparations applied to the breasts of mothers in the treatment of diseased nipples is another recorded source. Bouchet [4] observed poisoning in a 3 months infant, due to the use of a lead lotion on the nipple. Von Hove,[5] Roussel [6] and Holt [7] cite cases in which the nursing infant was poisoned by the application to the breast of an ointment containing lead acetate. Guerbet [8] observed lead poisoning in a 3 months infant secondary to the use of nursing bottles that had had lead incorporated into the glass. Dufour [2] mentioned instances of poisoning due to nursing bottle stoppers, both of metallic lead and of lead-containing rubber, and also from lead frames in which the nursing bottles were held. Medication of the infants' skin by lead plasters and lead dusting powder was the source of poisoning in the cases of Friedman [1] and Stephenson.[1] Veriot and Remy [9] observed lead intoxication in a 12 months infant due to the swallowing of a block of lead printers' type. Inhalation of lead dust, lead paint from a doll and clothing material impregnated with lead are given as sources of lead poisoning in infants of nursing age in the cases of Dufour.[2]

We have not found the use of lead nipple shields by nursing mothers previously demonstrated as a source of lead poisoning in infancy. Two such cases are the subject of this report.

REPORT OF CASES

CASE 1.—*History*.—A girl baby, white, aged 4½ months, was admitted to the Babies' Hospital, Nov. 3, 1923, because of vomiting, failure to gain in weight, and "nervousness," each of approximately one month's duration. The labor had been normal, and the birth weight 6 pounds 12 ounces (3 Kg.). There had been no previous illnesses. The child had gained regularly in weight, until the age of 3½ months, at the onset of the present trouble, when she weighed 12 pounds (5.4 Kg.). The child had been breast fed continuously until the time of admission.

She had vomited persistently during the last month. The vomiting was moderately forceful and occurred from two to three times each day. This was not related to feedings and had never been bilious or blood stained. There had never been abdominal colic.

The general nervousness began approximately simultaneously with the vomiting. The parents first noted that sudden, loud noises unduly upset her and that she became "jumpy after the slamming of doors or the dropping of a dish pan." She also became fretful and restless, particularly at night. She developed head rolling, and the hands, arms and legs were in motion most of the time. Forty-eight hours before admission, rightsided jerky movements began, and twenty-four hours before admission there were generalized twitchings. A slight stupor had been present for twenty-four hours. In the spinal fluid examination twenty-four hours before admission, clear fluid, 60 cells, a trace of globulin and the presence of sugar were reported. No paralysis or convulsions had been seen. She had gained no weight since the onset of the symptoms. The appetite had remained good. The baby had nursed vigorously throughout. The stools were normal in character and frequency.

Physical Examination.—The infant's measurements were: head circumference, 16¼ inches (41 cm.); chest, 15 inches (38 cm.); abdomen, 15 inches, and length, 23½ inches (59.6 cm.). The child lay in a slight stupor. The skin was free from eruption and its turgor good. The subcutaneous panniculus was scanty. There was generalized pallor. The glands were normal. The head was in the normal position without opisthotonos. The anterior fontanel was large, four fingerbreadths in diameter, tense, and definitely bulging. There was no craniotabes. The pupils and pupillary reflexes were normal. There was a bilateral, inconstant, horizontal nystagmus. The right ear drum was slightly congested. Chvostek's sign could not be elicited. The oral mucous membranes were pale without evidence of stomatitis, and a lead line was not visible. The neck was moderately spastic and not tender. Brudzinski's sign was not present. The thorax, abdomen and genitalia were normal. The extremities were spastic, with hyperactive deep reflexes. Positive bilateral Kernig's signs were obtained. Ankle clonus could not be elicited. Tache cérébrale was present. Twitchings of the extremities, reported in the history, were not present.

Electrical reaction was: anodal closing contraction, 3; anodal opening contraction, 10; cathodal closing contraction, 2.4, and cathodal opening contraction, 8.

The Pirquet skin test was negative.

Laboratory Findings.—The spinal fluid was slightly opalescent, with normal pressure, and contained 70 cells (80 per cent polymorphonuclears [?]); the globulin test was + + + +;

the sugar was 46 mg. per hundred cubic centimeters, and chlorides, 738 mg. per hundred cubic centimeters.

Blood examination showed: hemoglobin, 50 per cent; red blood cells, 2,500,000; white blood cells, 18,600; polymorphonuclears, 48 per cent; lymphocytes, 40 per cent; mononuclears, 2 per cent; eosinophilic polymorphonuclears, 1 per cent, and transitionals, 1 per cent. There was heavy and extensive stippling of the red blood cells. Several stipple cells were seen in each high power field. The urine was normal. The blood Wassermann reaction was negative.

The discovery of the stippled cells suggested lead poisoning. The mother was questioned again, and related that she had worn lead shields on both breasts continuously since the day of the patient's birth. No ointments or lotions had ever been used in conjunction with the shields. Before nursing she had, at times, washed the nipples with boric acid, but "more than half the time" the infant had been put to breast without any cleansing procedure. The mother had been free from symptoms throughout the infant's illness. Several specimens of the maternal blood showed no stippling of the erythrocytes.

Hospital Course.—The baby was weaned and was given potassium iodide, 2 grains (0.13 Gm.), every four hours during the twenty-three days she was in the hospital. There was an almost immediate improvement in the vomiting, which occurred only three times during the three weeks' observation. Excessive movements of the arms, hands, and legs were observed after the first examination. These nervous symptoms gradually subsided, with the exception of a series of convulsions on the eighteenth and nineteenth days after admission. They were associated with the purulent right otitis media and did not recur after myringotomy. The anemia persisted. Stippling of the red blood cells was observed on the seventh, twentieth and twenty-third days. Four later spinal fluid examinations were unsatisfactory, because of the presence of fresh blood in the specimens. The weight remained stationary while the patient was in the hospital. Chemical examination of the feces for lead was positive in one examination. Lead was not demonstrated in the urine or spinal fluid; it was found in the breast milk on two occasions. However, after careful cleansing of the breasts with ammonium acetate, lead could not be detected in the breast milk. We concluded that the lead was not being excreted in the milk, but that its source in the earlier examinations was the skin, and that the lead had contaminated the milk during the manipulation of pumping the breast.

Subsequent Course.—The patient has since been observed frequently, and is now 2½ years of age. The anemia has persisted. The hemoglobin at the thirtieth month is 35 per cent and the red blood cell count is 2,800,000. No stippling of the red cells has been seen since the sixth month, six weeks after the cessation of exposure to the shields. The child is underweight for her age, weighing 26 pounds (11.8 Kg.). Mentally she is normal. There is no evidence of foot drop or wrist drop.

Case 2.—*History.* A girl baby, aged 9 months, was seen in the outpatient department of the Babies' Hospital, Oct. 1, 1925, with a history of vomiting since the seventh month, pallor, and loss of weight since the seventh and a half month. The delivery had been normal, and the birth weight was 6 pounds 7 ounces (2.9 Kg.). There had been no previous illnesses. She had been fed exclusively from the breast, and had registered a regular gain in weight, reaching a maximum of 16 pounds (7.3 Kg.) at 7½ months. The growth and development had been normal. The head was held up at the fourth month, and she had manifested normal muscle power generally. Persistent vomiting had been present since the seventh month. It came on while the infant was still making a satisfactory gain in weight. It had had no relation to the taking of food, had been forceful, and had occurred two or three times each day. Neither bile nor blood had been seen in the vomitus. There had been no abdominal colic. The baby had had moderate constipation. The appetite had remained excellent. A pallor had been present for one and a half months. Previously, the baby's color was good. Since the onset of these symptoms, there had been a notable change in the mental attitude, which had consisted of a lessened tendency for the child to smile and play as she had done previously. She had remained quietly on her back most of the time with little interest in her surroundings. There had been no real stupor or convulsions. She had lost 2 pounds (0.9 Kg.) in the last six weeks.

The case was considered one of gastric indigestion due to improper nursing. Attempts to correct these symptoms by a regular regimen and instructions to the mother in correct nursing were not successful. After one month's observation, further questioning revealed that the mother had begun the use of lead nipple shields when the baby was 1 month old, and had worn them constantly since that time. There had been no medication of the nipples except cleansing them before each nursing with pledgets of cotton soaked in boric acid. The mother has had no symptoms suggestive of lead intoxication. The infant was admitted to the Babies' Hospital, Nov. 4, 1925, for confirmation of a provisional diagnosis of lead poisoning by Dr. C. A. Lang.

Physical Examination.—The infant's measurements were: head circumference, 17½ inches (43.8 cm.); chest, 15¼ inches (38 cm.); abdomen, 15¼ inches, and length, 26½ inches (67 cm.). The patient, aged 10 months, was poorly nourished, with a marked pallor. The palpebral fissures were widened, giving a staring facies. There were frequent quick grimaces. She lay on her back, apparently in no pain and without opisthotonos. The head was continually rolling from side to side. There were frequent clutching movements of the hands, and continual pronation and supination of the forearms, and jerky movements of the legs and feet. The anterior fontanel was 2 cm. in diameter, flat, and of normal tension. There was no craniotabes. The pupillary reflexes and the extra-ocular movements were normal. The mucous membranes of the mouth were clean; there was no stomatitis, and a lead line could not be made out in the gums. Chvostek's sign was not present. The neck was slightly spastic without tenderness. Brudzinski's sign was not present. The heart and lungs were normal. There was no abdominal tenderness. The liver was two fingerbreadths below the costal margin; the spleen was barely palpable. Tache cérébrale was not made out. There were frequent twitching and jerky movements in the extremities, as mentioned above, with moderate spasticity. The deep reflexes were exaggerated throughout. Kernig's sign was not present, and there was no ankle clonus. Trousseau's sign was not present. There was no tenderness of the nerve trunks, nor evidence of wrist and foot drop.

Blood Findings in Case 2

Day After Cessation of Exposure	Hemoglobin, per Cent	Red Blood Cells, per Cubic Millimeter	White Blood Cells, per Cubic Millimeter	Polymorphonuclears, per Cent	Lymphocytes, per Cent	Mononuclears, per Cent	Transitionals, per Cent	Nucleated Red Cells to 100 W. 13th	45	3,000,000	8,000	41	48	0	3	2	23,000	290,000
17th	45	2,700,000	10,000	49	43	3	5	0	3,000	170,000
20th	45	3,000,000	9,000	47	50	2	1	0	3,100	220,000
24th	45	2,900,000	15,000	62	36	1	1	0	2,300	190,000
27th	50	2,600,000	9,000	67	30	1	2	0	0	190,000
35th	50	3,400,000	14,000	46	45	5	4	2	0	250,000

Laboratory Findings.—Blood examination showed: hemoglobin, 45 per cent; red blood cells, 3,300,000; white blood cells, 18,000; platelets, 300,000; polymorphonuclears, 51 per cent; lymphocytes, 44 per cent; mononuclears, 5 per cent; transitionals, 2 per cent; nucleated red cells, 19 per hundred leukocytes. There was frequent stippling of the red cells (73,000 per cubic millimeter). The spinal fluid was clear with normal pressure, and contained: 60 cells (65 per cent lymphocytes); globulin + +; sugar, 78 mg. per hundred cubic centimeters (blood sugar, 103 mg.), and chlorides, 625 mg. per hundred cubic centimeters. The blood calcium was 11.1 mg. per hundred cubic centimeters. The blood phosphorus was 6.3 per hundred cubic centimeters. The urine was normal.

Subsequent Course.—The patient was under observation for a period of six weeks. She was weaned and given phenobarbital and sodium bromide by mouth. The frequency of the vomiting diminished almost immediately, averaging once every other day during the first two weeks, with complete cessation thereafter. She began to gain weight immediately, making a total gain of 2 pounds 6 ounces (1 Kg.) in six weeks. The jerky movements of the extremities, and the head rolling subsided gradually. There was only slight irritability after six weeks. The spinal fluid was normal on the twenty-fourth day.

Further spinal fluid examination the sixth day after admission showed: slight xanthochromia; normal pressure, 34 cells (90 per cent lymphocytes); globulin + +; sugar, 77 mg. per hundred cubic centimeters, and chlorides, 675 mg. per hundred cubic centimeters. The eighth day after admission, the fluid was clear, with normal pressure, and contained 26 cells (75 per cent lymphocytes); globulin + + +; sugar was present qualitatively. The twenty-fourth day after admission, examination showed: clear fluid; normal pressure; 4 cells; globulin, 0; sugar, 55 mg. per hundred cubic centimeters, and chloride, 700 mg. per hundred cubic centimeters.

It is noteworthy that the pleocytosis, the increased globulin, increased sugar and decreased chlorides returned to normal twenty-four days after the cessation of exposure to lead. There was no similar improvement in the anemia, as shown in the accompanying table. The rapid diminuation of the stippled cells and their disappearance on the twenty-fourth day is notable. Also the high nucleated red counts in the admission blood smear and on the third day are interesting. No stippled cells of the mother's erythrocytes were seen in several specimens.

Tests of hemolysis of the blood cells in hypotonic saline solution were done on the fifth and twenty-fifth days after admission. The test on the fifth day showed a moderately increased resistance to hemolysis in saline solution, while on the twenty-fifth day the hemolysis was identical with the control. The first finding is consistent with the observation of Aub and his co-workers.[10] The tests of hemolysis in the saline solution showed:

Fifth day after admission:
  Control: Initial hemolysis, 0.45 per cent sodium chloride; complete hemolysis, 0.35 per cent.
  Patient: Initial hemolysis, 0.45 per cent sodium chloride; complete hemolysis, 0.20 per cent.
Twenty-fifth day after admission:
  Control: Initial hemolysis, 0.45 per cent sodium chloride; complete hemolysis, 0.225.
  Patient: Initial hemolysis, 0.40 per cent sodium chloride; complete hemolysis, 0.225.

Chemical examination of the excreta showed 0.224 mg. of lead in the 2,560 cc. of urine collected in the interval between the tenth and the twenty-sixth days; 2.85 mg. of lead in the 65.5 Gm. of feces collected in the interval between the tenth and the twenty-sixth days.

The breast milk was negative for lead at several examinations.

COMMENT

The use of the lead shields on the maternal breast is the only tenable source of lead intoxication in our cases. The late onset excludes congenital poisoning. Excretion of lead in the breast milk is not probable in view of the negative chemical examinations of the milk, the absence of stippling in the maternal erythrocytes and of saturnism in the mothers, and the failure of the history to establish such sources as suspicious cosmetics and hair dye. Neither infant was fed from nursing bottles. Lotions and ointments were not used on the breasts in conjunction with the breast shields. Neither infant received treatment with lead-containing plaster or dusting powder. Careful questioning failed to reveal any source suggestive of lead toys, inhalation of lead dust, lead impregnated clothing, or of lead foreign bodies in the stomach.

The clinical picture in both cases was that of vomiting, meningeal irritation and anemia. Clinically, these symptoms had no characteristics sufficiently distinctive to differentiate them from like symptoms in more common diseases. There was no clinical evidence that the vomiting in these cases was different from that seen in gastric indigestion; the nervous irritability clinically was indistinguishable from the meningeal irritation seen in other forms of meningitis and meningo-encephalitis; the anemia was identical, clinically, with anemias secondary to chronic disease and malnutrition. None of the manifestations in the classic lead triad were present—colic, palsy and the presence of a lead line in the gingival mucous membranes. This suggests that, in nursing infants, lead poisoning is probably too seldom considered as a diagnostic possibility when such common symptoms as vomiting, general nervousness and anemia constitute the clinical picture. The history of a source of lead, basophilic degeneration of the red blood cells, the changes in the spinal fluid, and the chemical detection of lead in the excreta were the most valuable aids and the final proofs in the diagnosis of lead poisoning in our cases.

The presence of lead in the feces of both patients demonstrates that lead in appreciable quantities may be ingested by infants suckling breasts which have been exposed to lead shields. The detection of lead in the urine in case 2 is absolute evidence that after ingestion from this source lead can be absorbed into the blood stream[10] and, in our cases, in sufficient amounts to affect the blood and to cause changes in the spinal fluid. These findings warrant the conclusion that lead poisoning in both patients was caused by the use of lead nipple shields.

Personal communication with obstetricians in New York testifies that the lead nipple shield is a commonly employed therapeutic measure in both dispensary and private practice. The duration of the use of the shields is usually less than one month, and a careful washing of the nipples previous to each nursing is advised. Under such conditions, there has been apparently no intoxication in the nurslings. In our cases the period of exposure to lead was several months—in case 1, three and a half months, and in case 2, six and a half months. The first mother was negligent in washing her nipples. The most important factors in the development of lead poisoning from the use of the shields are probably the length of exposure, the care of the nipples previous to nursing, the vigor of the sucking movements of the infant, and perhaps the individual susceptibility to lead which was noted by the Australian observers in older children.[11]

There is no indication in our cases that the use of lead shields for two or three weeks can cause lead intoxication. However, our cases do demonstrate that the lead nipple shield is a definite source of danger to the nursing infant if used for longer periods, and that, if the control of the mothers by the physician is not sufficient to insure the discontinuance of the shields after a few weeks, other therapeutic measures should be used in the treatment of the diseased nipples.

Clinical Notes, Suggestions, and New Instruments

FIXATION OF FRACTURES OF THE CLAVICLE: ANOTHER METHOD

J. E. M. Thomson, M.D., Lincoln, Neb.

My object here is to describe a technic of applying fixation to fractures of the clavicle, using old and well tried principles, with especial reference to fractures of the outer third of the clavicle.

Most textbooks on fractures deal lightly with the possibilities and prognosis of fractures of the clavicle. Alinement and apposition, according to various writers, mean little to the ultimate outcome of the case. The primary object of all fixation is to hold the shoulder of the affected side well back and up. The T splint, cross or barrel stay application of fixation offers an excellent medium for holding these fragments. However, in my experience most of these fractures have been in men, and it has been extremely difficult to keep the splints in proper position. They demand constant attention and adjusting. In several instances, satisfactory position of the fragments has been lost to a certain extent by loosening of the bandages or straps during the first few days after their application.

It is true that fractures near the sternal articulation of the clavicle are not likely to cause any appreciable disability, provided the fragments do not injure the underlying soft tissues. However, our attention has been attracted to the severe shoulder disabilities resulting from fractures of the outer end of the clavicle, particularly those near the scapular articulation which have not been adequately reduced and immobilized. Such fractures are often seen complicated by dislocations of the head of the humerus, separations and dislocations of the acromioclavicular articulation, fractures of the scapula, and injuries of the glenoid cavity and shoulder joint. In my experience, nearly all fractures of the outer third of the clavicle are associated with injuries about the glenoid cavity, and there is always an abnormal mobility in the acromioclavicular articulation.

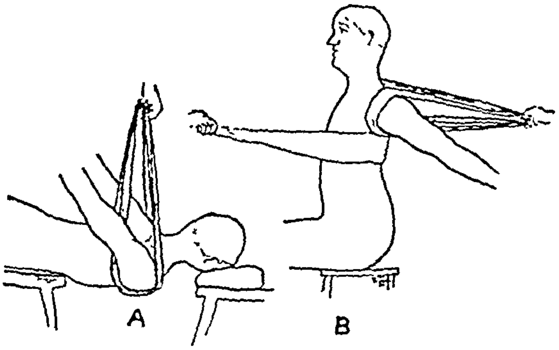

Fig. 1.—*A*, patient swung between two tables, muslin strips supporting the shoulders and held over head by assistant, the arms held well back and up; *B*, patient sitting, muslin straps over shoulders held from behind by assistant, countertraction maintained by muslin strap high up across back and held in front while the arms are held well back and up.

The common disability that results from the improper treatment of the latter type of fracture of the clavicle consists of painful abduction of the arm from the body, and limitation of movement forward of the humerus and backward when the patient attempts to put the arm behind him. Often very vigorous physiotherapy does not entirely relieve the symptoms, and permanent disability develops.

It has been my practice in the treatment of fractures of the clavicle to pad the shoulders and the axilla with the figure-of-eight sheet wadding bandage. The patient seated, if general anesthetic is not necessary, or on his face swung between two tables as illustrated, should an anesthetic be needed, with muslin bandages across the front of the shoulders and held from behind or above as the case may be, sitting or lying, the arms abducted up and backward.

When the patient is sitting, a counter traction is made by muslin bandages across the back up high and held by an assistant in front of the patient. However, when the patient is lying down the weight of the body is sufficient countertraction for ordinary reduction of the fracture.

After the sheet wadding bandage has been applied over both shoulders, a light plaster-of-paris figure-of-eight cast is applied to both shoulders and about the chest. This can be cut out considerably without weakening the fixing power of the cast.

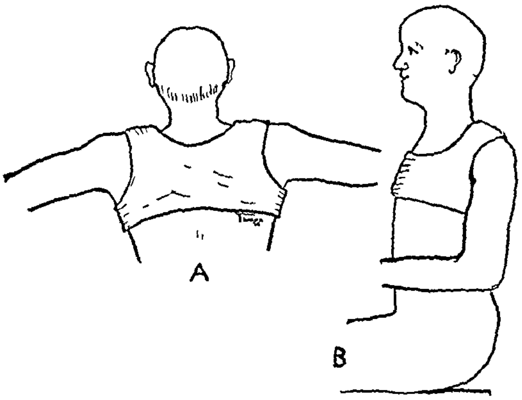

Fig. 2.—Figure of eight cast applied. *A*, seen from rear, *B*, from side.

When the fracture of the clavicle is in the outer third, the plaster-of-paris cast is extended down over the chest, embracing the entire trunk. The arm on the affected side is held well back and embedded in the plaster, forming a body and arm spica with the arm at 90 degrees of abduction, with the body and forearm flexed to an angle of 90 degrees with the arm and in the same plane, held in supination, the hand in dorsiflexion.

In the figure-of-eight plaster cast the patient has full freedom of the arms without jeopardizing the possibility of losing the position of the fragments. If the fragments are not in sufficiently satisfactory alinement, through an opening in the cast, direct leverage of the fragments with a small instrument can be accomplished to bring the desired position, or open operation if deemed necessary may be performed. Such procedures, however, are seldom necessary.

At the end of four weeks the cast is removed, and a muslin bandage reenforced with adhesive plaster will often be enough immobilization until the patient is ready to be relieved from all fixation devices.

In those cases in which the fracture is of the outer end of the clavicle, the arm and the body are placed in a spica. The upper part of the arm cast is removed at the end of two and one-half weeks, and massage, manipulation and physiotherapy are instituted for the arm and shoulder joint, the arm always being left in the well abducted position. At the end of four weeks the entire cast is removed and physiotherapy is continued, the muslin bandage reenforced with adhesive plaster being the only limiting feature to the shoulder region for another week or so.

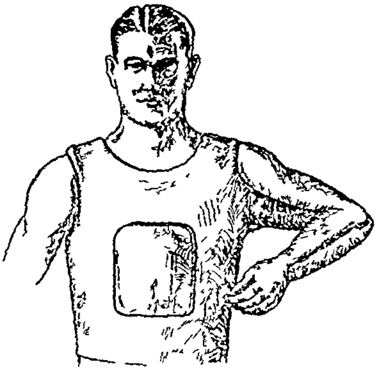

Fig. 3.—Body and arm spica used in cases of fracture of the clavicle in the outer third with injury to the shoulder joint, the top portion of the arm cast has been taken off, that physiotherapy may be instituted.

When this method is followed, the shoulder joint has an opportunity to heal as well as the fracture fragments, and there is not the long period of painful shoulder disabilities that are found so often in cases referred to us after having been treated by other methods of fixation.

I have had one patient who was a football player and who, after the second week in his figure-of-eight plaster cast, continued the major part of his practice and was used after the third week in a game without injury to the position of the fragments; but such strenuous testing of the fates is not desirable, even in a cast.

BILATERAL GONORRHEAL SALPINGITIS IN A CHILD THREE DAYS AFTER INITIAL INFECTION

Minas Joannides, M.D., Chicago

This case is reported because it presents the following important features: A girl, aged 6½ years, was infected innocently by a careless mother; the disease spread into the tubes and the pelvic peritoneum within three days after the initial infection, and the child recovered after double salpingectomy and appendectomy with drainage.

The child was living at home when the mother was infected with gonorrheal vaginitis and endocervitis. Although the mother was warned against careless handling of her three girls and two boys, ranging between the ages of 3 and 10 years, this child did not escape. She had a strong desire to urinate when at school, but the teacher did not allow her to go out of the room, with the consequent result that she soiled herself. Ever since babyhood, she had had poor control of her bladder sphincter. On going home she was cleaned by the mother, who had just previously taken a local treatment at home and forgot to use an antiseptic for her hands. On the following day the girl noticed a discharge from the vagina, but the mother paid no attention to it. Two days later the girl became very sick, with fever ranging at the level of 103 F. There were vomiting, pain in the abdomen, and a very profuse vaginal discharge.

When seen, the child had bilateral rigidity in both lower quadrants, there being more rigidity on the right side and over the appendix. She had severe nausea and vomiting. There was a thick purulent vaginal and urethral discharge. The pulse ranged between 140 and 160 a minute. She was immediately taken to the Deaconess Hospital in Minneapolis, where she was placed in the Fowler position, with cold applications over the lower part of the abdomen. During the night the child's pulse began to get thready, and the temperature persisted at its previous high level. By 5 o'clock the next morning, the child was moribund, and in order to lessen the responsibility on myself, Dr. C. A. Witham was also called to see her. He concurred with my decision for immediate laparotomy, in spite of her critical condition. Under ether anesthesia, a midline incision was made from the pubis to the umbilicus. On opening the abdomen, I noticed some serous fluid in the pelvis but no tendency to any adhesive reaction as yet. The peritoneum as well as the uterus and tubes and also the appendix presented a fiery red injection, as if there was a beginning gangrene of the organs. There were no adhesions between the appendix and the neighboring viscera. There was a thin purulent discharge that could be squeezed out of the tubes when the latter were handled. Both the tubes were removed, along with the appendix. The ovaries were not sacrificed in the hope that, though involved, they might offer more help by their internal secretion than harm by their inflammation. A hurried closure was made after ample drainage had been established.

The child had a stormy postoperative course for the first two days, but by the third day the temperature had dropped to 99.8 F., and remained along that level until she was discharged from the hospital seventeen days after operation. There was a profuse discharge of pus from the wound, which was irrigated daily with mercurochrome-220 soluble (2 per cent watery solution). Vaginal instillations were given also twice daily. No sinus was present four weeks after the operation, although there was a small granulating wound about 25 mm. in diameter at the time when last seen. The vaginal discharge became minimal, but the instillations of mercurochrome solution were continued daily till the child had no more discharge. Fortunately, the rest of the children were normal on repeated examinations.

The lessons from this case are clear: We must emphasize to the infected parents the dangers of infection in the children. With the removal of the tubes and the infected appendix, it was easy to cure the child by establishing ample drainage and giving antiseptic therapy.

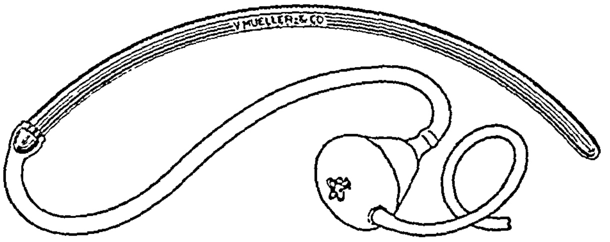
A NEW INSTRUMENT FOR THE INTRODUCTION OF HEMOSTATIC BAGS IN SUPRAPUBIC PROSTATECTOMY

E. O. Swartz, M.D., Cincinnati
Attending Urologist, Cincinnati General Hospital and Jewish Hospital

The control of hemorrhage following the removal of a prostatic adenoma by either the perineal or the suprapubic approach is the anxious concern of every operator. The popularity of the hemostatic bags of either the Hagner or Pilcher model attests their effectiveness. The use of these bags is almost entirely confined to those who remove the prostatic obstruction suprapubically.

The bladder is opened by median section, the adenoma removed by blunt dissection. A special sound with a Benique curve and a notched tip is then introduced through the urethra into the bladder and the bag threaded onto the tip of the sound. The rubber may or may not be held to the sound by means of a ligature. The sound is then slowly withdrawn through the urethra, pulling the bag down into the cavity left by the removal of the adenoma. The bag is inflated with fluid or air and held in place by means of adhesive plaster.



Sound for the retrograde introduction of a hemostatic bag into the prostatic cavity, with a Pilcher bag fastened to it.

This is about the method used in most cases. We have at times experienced considerable difficulty in maintaining a rigid aseptic technic during the introduction of the sound through the urethra. We have also felt that the passage of the sound through the urethra, which is seldom sterile, into the raw cavity from which the prostatic adenoma was removed may be the means of introducing fresh infection into the denuded area in the bladder and prostatic urethra. To overcome these objections and facilitate the introduction of the various types of hemostatic bags, the special sound here presented was designed. A number of different shapes, curves and sizes were tried out before one was found to be satisfactory.

The instrument is a one-fourth segment of the diameter of a circle about 14 inches in diameter. In calliber it is a no. 23 F. with a special tip no. 17 F. over which the bag is threaded. The opposite end is rounded and tapered for ease of introduction into the urethra. After the enucleation of the prostatic obstruction, the bag is threaded on the tip and the rounded opposite end of the sound inserted through the bladder and the prostatic cavity into the urethra. The sound is pushed on through the urethra and out the meatus, carrying the bag into the prostatic cavity. Occasionally the procedure is varied by introducing the sound into the urethra retrograde from the bladder, and while it is in place enucleating the prostate from around it.

By either of these methods the unsurgical procedure of introducing a sound through the urethra into the raw prostatic cavity is done away with and the danger of infection lessened.

The instrument was made by V. Mueller & Company after a number of experimental models were tried out.

By the use of this sound retrograde we have been able to maintain a better aseptic technic and introduce the bag with greater facility than by the use of the older type sound.

RELIGIOUS HEALING

PRELIMINARY REPORT *

ALICE E. PAULSEN, Ph.D.
NEW YORK

In ancient times the practice of healing was carried on by the priesthood. It was a recognized function of religious procedure, and history supplies us with amusing accounts of the queer charms, incantations and magical practices of every conceivable sort that were part of the stock in trade of the healers of those days. Such practices survive to this day among primitive peoples.

Though the early Egyptians had some knowledge of anatomy and must have known something about hygienic methods, the separation of medicine from religion and magic did not occur until the fourth century before Christ. Hippocrates, the father of modern medicine, was a product of the comparatively highly cultured Greek civilization, which made bodily perfection and health ideals in themselves.

Modern medicine itself has gone through endless changes. When we think of the numberless remedies that have been heralded, assiduously applied and later proved worthless, in spite of their one-time reputability and popularity, we are sometimes forced to the conclusion that in the history of medicine there have been many practices, which, whatever they accomplished or failed to accomplish, must have worked through suggestion and not through any intrinsic therapeutic value. They take their place with magic. Nevertheless, the steady increase in the body of medical knowledge has tended to separate medicine further and further from religion, until at the present time we are scarcely able to trace the earlier close connection.

Psychotherapy is demonstrating the need for a more thoughtful consideration of Plato's ideal "mens sana in corpore sano" in the treatment of all disease conditions, and in a general way the interrelation of mind and body is recognized. But with regard to religion, a most vital aspect of mental life, opinion is decidedly divided.

A part of this particular study included gathering opinion, from a more or less unselected group of physicians, concerning the value of religion as a therapeutic agent as judged by their experience with it in practice. Comparatively few had found it practical or had had sufficient experience to warrant expressing an opinion. Of those who had had experience with it, some reported favorably, some unfavorably. The same was true in the case of those who expressed opinions on the basis of a theoretical consideration of the question.

Yet Plato's "mens sana" apparently meant something more than a "sound mind" as it is commonly translated, and as psychotherapy ordinarily interprets it. He[1] says: "The office of the physician extends equally to the purification of mind and body. To neglect the one is to expose the other to evident peril. It is not only the body which, by sound constitution strengthens the *soul*, but the well regulated *soul*, by its authoritative power, maintains the body in perfect health."

Today, medicine freed from the church appears to have left the care of this much disputed soul of man to the care of theology. Theology on its part has made little of the body. As a matter of fact, for about 1,500 years the church and its authorities were a hindrance to the progress of science in general. Christ emphasized healing of the body in his ministry, but, during the middle ages especially, his followers became so perverted in their thought that they brought about untold damage to the healing art, at a most important period of its development, through their tragic undervaluation of bodily welfare and overestimation of spiritual values.

The church, however, has gone through radical changes since that time. There are those who believe that even now it is experiencing a sort of continuous and gradual revolution, destined to emerge with a reversal of its former attitude toward science. Instead of looking on it as a rival, the church is beginning to welcome science as an ally and is seeking its aid in solving the problems that confront organized religion today.

Science, on the other hand, is said to be becoming less material, less convinced that the universe can ultimately be explained in terms of matter, and more ready to enter speculative fields.

As problems become mutual, all tend to meet in the course of their search for truth. And so it is with medicine and religion in relation to the present problem. We are not concerned with the differences between religion and science, the science or art of medicine in particular, but with what each can contribute to an impartial investigation of a mutual problem, namely, the relation of religion and health, as demonstrated in certain modern religious-therapeutic practices.

In order to comprehend the situation fully it is necessary first to consider the theories and practices involved in the activities of certain cults, not within the church, which include healing in their purpose and give their systems a religious setting.

Then we must consider the work of individuals and institutions not especially organized for religious work but making religion an essential element in the methods they use to readjust patients of various types who are under their care for that purpose.

We come finally to a consideration of work within the churches. This includes organized efforts to introduce healing as a function of religion, less direct efforts at religious therapy on the part of individual members of the clergy, and certain types of medical work carried on in established relationships between clergymen and physicians. To complete the picture, we call attention also to health work along more ordinary lines and the general facilities available for health work in churches.

The problem is of such complexity that it will be fully comprehended only through a most intensive study carried on with mutual understanding, mutual cooperation and mutual desire to solve the questions involved. This is a matter for the future. Under the circumstances, the present study constitutes only a preliminary survey of the field, and my purpose in this paper is merely to indicate the scope of the problem, to formulate conclusions so far as conclusions can be formulated at this stage, and to present what material I have been able to glean, as a basis for the formation of adequate plans for a more adequate investigation of the entire situation. Subsequent papers will report the results of further study.

The survey has served to establish the fact that the problem is very great and that it will repay further investigation both because of its possibilities for good and on account of the obvious necessity of preventing evil developments. Since the movement is world wide, it was necessary to localize this particular survey in order to make it practical. It has therefore been confined largely to movements that have active centers in New York. A perusal of the literature on the subject will readily verify the fact that what is reported here is typical of what may be found throughout the country.

* Prepared under the auspices of the Committee on Public Health Relations of the New York Academy of Medicine.

[1] Plato, quoted by Atkins, G. G: Modern Religious Cults and Movements, New York, Fleming H. Revell Company, 1923, p. 98.

Its importance may be judged from the fact that the Church of England, after a study of the problems presented by the religious healing movement, carried on over a period of three years, has appointed a permanent committee of prominent physicians, clergymen and psychologists to act in an advisory capacity to the church with regard to the matter, and in America the Episcopal Church has also appointed an advisory committee consisting of physicians, clergymen and laymen. There is no doubt that the movement is on, and on in earnest.

INDEPENDENT MOVEMENTS

CHRISTIAN SCIENCE

The most highly organized modern "faith cure" movement is admittedly Christian Science. This cult is said to comprise about 1,500,000 members. According to the statistics published in the *Christian Science Sentinel*[2] following the annual convention of the Christian Science church in June, 1925, the work founded by Mrs. Mary Baker G. Eddy, about 1870, is now being carried on by 7,220 recognized practitioners. Efforts are being made to secure nurses who will pledge themselves to faithful cooperation with practitioners, and there are now 216 on register. In the course of the year, 1,600 patients were treated at the newly established Christian Science sanatorium.

During the year, 3,257 public lectures on the teachings of Christian Science were given. Of these, 312 were given in foreign fields. The total public attendance at these lectures was 2,580,160 people.

The yearly receipts of the mother church were $1,075,496.33. Besides this there were gifts to the "special fund" amounting to $468,218.89; to the "relief fund," $202,103.07; to the "benevolent fund," $430,384.98, and to the "permanent fund," $17,868.08. So firmly is this movement established, both financially and in numbers, that its authorities were able to obtain property for it in the vicinity of the mother church in Boston valued at $1,305,755.47 with only $200,000 invested in cash.

Christian Science is primarily occupied with the problem of treatment. Students of philosophy and of religion harshly criticize the philosophical and religious setting which has been given to Mrs. Eddy's theories and do not recognize Christian Science either as a philosophy or as a religion.

In 1862, Mrs. Eddy, a confirmed neuropath,[3] who had been a more or less helpless invalid since her early childhood, went to Portland, Maine, to consult one Phineas Parkhurst Quimby, who, though only a watchmaker by trade, had built up a rather elaborate "mind cure" based on the theories held by the French "animal magnetists" of that time. Quimby's interest in these matters was aroused by the lectures and teachings of a magnetizer named Charles Poyen, who visited the United States about 1840.

After a few treatments by "Dr." Quimby, Mrs. Eddy appeared to be completely well. She was convinced that he had cured her of paralysis which, she believed, had been due to a lesion of the spinal cord. Following her cure she devoted herself to the study of Quimby's methods and teachings, and Christian Science is the outcome of her study. Her first publication was copyrighted in 1870, and in 1875 she published "Science and Health," which contains the authoritative creed of the organization. "Science and Health with Key to the Scriptures" is the complete title of this book as it now appears. Mrs. Eddy devoted the rest of her life, until her death in 1910, to the advancement of Christian Science through her writings.

Certain other students of Quimby accused the founder of Christian Science of having deliberately stolen the material for her own publications from some of their teacher's unpublished manuscripts with which she was familiar. These, like Mrs. Eddy's, were curious mixtures of ideas gleaned from the Scriptures, spiritualism, clairvoyance, treatises on disease, happiness, wisdom, science and the arts. Mrs. Eddy indignantly denied any plagiarism, and, apparently quite unmindful of the now accepted theories concerning such phenomena, claimed that her work was more than original in that it was accomplished by divine inspiration, some of it produced by automatic writing.

The main tenets of her teachings are to be found in "Science and Health with Key to the Scriptures." The basic maxims are:[4]

1. God is All-in-all.
2. God is good. Good is Mind.
3. God, Spirit, being all, nothing is matter.

To the Christian Scientist, "matter is nothing beyond an image of mortal mind." "Disease, death, evil, sin deny good, omnipotent God, Life." Nothing is real and eternal, nothing is Spirit, but God and His idea. "Evil has no reality . . . it is simply a belief, an illusion of material sense."[5] Sickness is "error."

The "scientist" treats himself with these thoughts. He believes that pessimism leads to weakness, optimism to power. If he is ill, his self-treatment consists in dwelling on those parts of Mrs. Eddy's teachings which are appropriate for his condition, devoting his entire conscious activity or passively giving himself up to steadfast denial of the reality of the "error" to which he may temporarily be subjected. This is varied with prayer, audibly expressed or silent, and affirmations of goodness.

If unable to treat himself, he calls on a practitioner, who may help him either by absent or personal treatment. Absent treatment does not require that the practitioner shall see the patient. He may be appraised of the patient's need by telephone, telegraph or other communication, and carries on treatment wherever he may be. Some practitioners and some patients state that they are so *en rapport* that no material communication is necessary to appraise the practitioner of the patient's need, and the patient as through telepathy becomes aware that the practitioner is meeting his need. The patient need merely place himself in a receptive attitude, and healing will follow as a matter of course.

When the practitioner treats a patient in person, efforts are made first to bring about the proper attitude of mind in each. The practitioner directs his efforts toward placing the patient *en rapport* with and under the control of the Divine Mind. All else must be banished from his mind. The patient must relax and banish all fear and misgiving, expect to be healed and maintain a passive receptive attitude.

[4] Science and Health, p. 113, lines 16, 17 and 18.

[5] Quotations from Science and Health with Key to the Scriptures.

This attitude is brought about largely by persuasion in the case of new patients, but the adept is trained to assume it with little difficulty. Treatment proper consists of reading or quoting suitable passages from Mrs. Eddy's writings, meditations, repeated denial of the reality of the patient's symptoms if he is being treated for health, with affirmations of health, perfection, goodness and suitable prayers. The treatment may be silent, audible or partly silent and partly audible, and may vary in length of time from a few moments to several hours The fee for service is as a rule on the basis of free will offering, with a tacit understanding that it shall be in proportion to the patient's means and the service rendered.

No medical help is permitted beyond attention to ordinary hygienic measures, and in her earlier teachings Mrs Eddy deliberately enjoined against even these A practitioner is not permitted to treat a case unless the patient has chosen between his ministrations and those of the medical practitioner. Most practitioners demand that the patient himself shall desire and ask for his services, but some still consent to attempt winning the individual at the request of others interested in him, however resistive the patient himself may be at first

For no ailment is definite diagnosis previous to treatment considered necessary, nor is evidence of cure demanded beyond the patient's testimony. To avoid difficulty from the legal point of view, a physician is called in if death appears imminent. Christian Science practitioners are not required to have medical training, nor is there an academic requirement of any sort, beyond the acquisition of certain foundations in the technic of Christian Science treatment and personal qualifications satisfactory to the Christian Science authorities, by which they are officially recognized.

The Christian Scientist places great emphasis on the effect of suggestion in general. He has an almost superstitious abhorrence of any negative thought, making a practice of banishing at once every idea of disease, misfortune, unhappiness or "error" of any sort. He does not wish people even to mention them in his presence He endeavors to create for himself a cheerful, pleasant, happy environment and to think only positive, constructive thoughts. The practitioner makes a point of demanding a cheerful atmosphere and the creation of "harmony" in the sickroom

Besides attending their regular church services on Sunday, treating themselves or taking treatment from practitioners when in "error" of one kind or another, attending midweek experience meetings at which they may bear public witness to the help they have received through the application of Christian Science in the pursuit of health, wealth and happiness, the followers of Mrs Eddy, if they are faithful, spend time in the daily study of her "word." A daily lesson based on the study of Science and Health with Key to the Scriptures is provided for this purpose.

A well organized bureau supervises the publication of Christian Science literature. Lectures and other publicity are carefully planned Two publications edited with Christian Science principles in mind, the *Christian Science Monitor,* a daily newspaper, regarded by many as one of the best dailies in the country, and a weekly, the *Christian Science Sentinel,* have a wide circulation among the general public

JEWISH SCIENCE

Similar to Christian Science, but of more recent origin, is Jewish Science,[6] *founded by Rabbi Morris Lichtenstein* New York has several active Jewish Science centers, including a prayer clinic

"Jewish Science prayers," says Rabbi Lichtenstein, in "Jewish Science and Health," "are always answered " Further quotations from the same source make clear the similarity between this cult and others of the same nature The methods advocated are typical.

How to Pray —"The Divine Mind communicates with the human mind through the imagination. . . .

"A prayer therefore should be offered in the form of a mental image Man must visualize the thing he desires, he must use his imaginative powers to form his petition in terms clearly outlined in his own mind The profound concentration of attention and thought which this form of prayer requires fills also the heart with deep earnestness and devotion Man must pray whole heartedly as well as whole mindedly; he must believe in his heart that his well being depends completely upon his prayer

"In these mental prayers there should never be formed any negative images . . one should see with his mental vision only the state in which he desires to be he must keep the image alive and fresh, which means that this image prayer must be frequently repeated, each time with greater clearness and with deeper devotion The mind . must be free from doubt and hesitation and should sincerely expect a response to its supplication. The answer will not fail to come

"One must first of all put himself into a calm state of mind . . must free himself of all distressing thought and unpleasant feeling . . become serene and thus attuned to the Divine Mind Serenity cannot be achieved without bodily relaxation. Therefore one should relax completely, put himself perfectly at ease, feel no discomfort, then close his eyes and offer his prayer with the imagination Gradually and with concentrated effort, the mind will succeed in presenting its prayer

"Should the petitioner find himself unable to visualize his supplication, he may bring words to his assistance and offer his petition in the form of an affirmation An affirmation is a prayer offered to the Divine Mind in affirmative terms When one suffers from unhappiness, he affirms.

" 'The Divine Mind in me expresses itself in happiness ' When one is steeped in despondency he affirms 'I am filled with Divine hope and cheer ' *In this as in* the other method of prayer—that of the mental image—the mind of the supplicant must be attuned to the mood of the Divine Mind . . .

"In both methods of prayer, the visualized and the affirmative, the supplicant must realize fully that he is declaring his desires to the Divine Mind and that his prayer will always be fulfilled. . . ."

Healing —"The greatest gift in man's possession is health . . . Because health is natural to man he need not exert himself to attain it; he need have only a care to preserve it. Health can best be preserved and life prolonged by following faithfully the precepts of Jewish Science We say 'Live serenely . . . avoid unwholesome excitement . . . live peacefully, and avoid anger . . . live cheerfully, avoid moroseness . . . be contented, avoid envy . . . love every one, hate no one . . . be hopeful, courageous, never worry, never fear . . . above all trust God at all times . . . wholeheartedly . . . with all your soul . . . your might . . . and you will come to know that your life is inherently a part of his essence and that your mind, therefore, is not made to be a harbor of destructive influence, nor your body a place of refuge for pain and suffering. . . .'"

---

[6] Lichtenstein, Morris Jewish Science and Health, New York, Jewish Science Publishing Company, 1925

A prayer for health is offered in a manner akin to the prayer offered for any other need . . . consists of two parts: first, the visualization of divine giving and then of man's receiving; first, the process of healing; second, the state of health restored through that process.

"If any particular organ of the body is affected, the affirmation must declare that health is saturating it, obliterating all defection and suffering. . . . If the heart is affected . . . affirm 'the stream of Divine Health is flowing into my heart, filling it with abundant health. . . .' This formula may be modified to be applied also when the ailment is in the lungs, digestive organs, liver, kidneys . . . any part of the body, care being taken to name the given part distinctly. As in all prayer, relaxation, freedom from strain and distraction is cautioned. The author further directs, 'Repeat the affirmation a number of times, slowly, without the urge of making many repetitions, but rather with concentration and emphasis on each word.'" The prayer should occupy about fifteen minutes.

Directions are also given for prayers for others, with the patient either present or absent.

"The method of praying for others is akin to that of praying for oneself. Both the ailing and the one who prays enter into deep silence. They both relax completely, eliminating all tension from body and mind. They both close their eyes; but while the mind of the patient becomes perfectly passive and inactive, that of the supplicant becomes awake and active. He must visualize the patient as the recipient of God's blessing." This prayer should also last fifteen minutes.

"A prayer for help may be offered either in the presence or absence of the ailing and distressed . . . it is essential that the prayer in the absence of the ailing should be offered in the same manner and with the same devotion as a prayer offered in his presence . . . first visualize him as present . . . seated opposite . . . relaxed . . . have a clear impression of his appearance . . . having previously obtained knowledge of his abode, name, approximate age . . . general appearance . . . and if possible procure a likeness. The necessary part of the absent prayer is the identification of the one prayer for . . . mention name and location at outset of petition. It is best that the ailing one should be aware of the fact that some one is offering prayer for his restoration . . . more advantageous that he be informed of exact hour that prayer is to be offered and that during that period he close his eyes and place himself in a state of perfect ease and relaxation . . . think of Divine Healing permeating him, restoring to perfect health."

"After each prayer," the author states, "definite changes for the better will take place in his condition; pain will become less intense each time, strength will supplant weakness, hope will replace despondency, and well being will be regained."

NEW THOUGHT

As a matter of fact, the term New Thought covers the teachings of all the modern healing cults, including Christian Science, Jewish Science and those still to be discussed. Moreover, the "thought" is as old as philosophy itself. Its modern advocates differ only in the manner in which their systems present it. As the systems become more highly organized, they tend to form separate cults and to work more or less independently, although many, if they qualify, become members in some such organization as the International New Thought Alliance or other centralizing agency. However, none of the other New Thought movements are as unified as Christian Science, a product of the same parent stem.

The entire movement in this country may be traced to the revival of transcendentalism which took place in New England in the early part of the nineteenth century. Contemporary thought at that time went through an upheaval under the influence of a keen interest in Neo-Platonism, with its attendant renewal of interest in mysticism, idealism and particularly the idea of an immanent God.

In 1830 there was formed a rather loosely organized "Transcendental Movement" largely composed of the followers of such writers as Emerson, Channing, Ripley, Margaret Fuller, Brownson and Hedge. Emerson's essay on the "Over Soul" gives the essence of this movement, a combination of the influence of the Orient and ancient Greece.

This has been passed on to New Thought, and to it has been added the influence of the so-called "New Psychology,"[7] which is differentiated from modern empiric psychology by its comparative lack of scientific method and its interest in transcendentalism, which the latter has left practically untouched.

Modern New Thought is also influenced by the doctrines of Theosophy concerning reincarnation, telepathy and the like.

The fundamental principle underlying all New Thought ideas is that "there exists an infinite and eternal spiritual Principle of Being"[8] to which are attributed the qualities of "omnipotence, omniscience, omnipresence."

"This Principle of Being is regarded as Pure Spirit . . . the essence of Spirit being Mind. . . . The Principle of Being is spoken of as Universal Mind. Its substance is regarded as Mental Substance. Its power is regarded as Mental Power. From this arises the statement that 'All is Mind,' including the manifestations, emanation or expression of Mind."

Furthermore, "This principle of Being is held to be One and one only. There being nothing in existence other than this One Principle, the universe must be regarded as necessarily an emanation, manifestation or expression of the One Principle of Being. There is nothing else for us to be. Moreover, the One Principle of Being must be immanent in everything, in different degrees of expression and manifestation."

Thus, if we are ill, unhappy, unsuccessful, it is because we are not manifesting this "Power Within," and it behooves us to take steps to put ourselves "in tune with the Infinite." This may be accomplished according to some New Thought teachers by simply relaxing, thus removing the inhibitions from the flow of energy stored in the mind. Others believe that the mind is influenced by the Infinite Mind and, by making it receptive, energy from without flows in to satisfy whatever need is present. Some compare the individual mind to a radio instrument. Its function is to receive energy radiating from the Divine Mind. Tuning in is a process of controlling the vibration rate of the receiving instrument that it may pick up the vibrations from the Infinite.

---

[7] This should not be confused with the term "New Psychology" as used in more scientific circles. It is doubtful whether the more popular form has any right to the name.

[8] Atkinson, W. W.: History and Principles of New Thought. Holyoke, Mass., Elizabeth Towne Publishing Company.

Practically all are agreed that the "subconscious mind" is either the storehouse of infinite energy or the instrument which must be manipulated in order that the individual may manifest the qualities of the Infinite Spirit of which he is but an emanation. Proceeding on this theory, innumerable methods of developing, stimulating or releasing the forces of the subconscious mind, as well as methods of tuning in with the Infinite for one purpose or another, are proposed. Thus, we find teachers giving lectures followed by private courses and individual instruction in such things as "Concentration," "Relaxation," "How to Manifest," "How to Demonstrate," "Releasing the Forces of the Subconscious Mind," "How to Visualize," "How to get Anything you Want," "How to Stop Worrying," and "How to Succeed."

Treatment varies with the school and may consist of relaxation with the realization of the desired end in mind, verbal treatment with New Thought principles, as expressed by various New Thought writers, or passages from the Scriptures, meditation, visualization of the desired end as recommended in the case of Jewish Science prayers, active or passive repetition with attention wholly concentrated on certain New Thought formulas, such as in case one wishes to manifest health, "I am Well!" "I am Strong!" Prayer of the affirmative type also has an important place.

Music, rhythmic exercises, special types of voice culture, "vitalic" breathing, cultivation of one's special talents in order to better express oneself all have their advocates, each professing to have a special influence over the latent powers that need only be released to emancipate the spirit of man. This is sought to the end that one may manifest more abundantly.

The New Thought student is thoroughly convinced of the influence of mind and he therefore "guards the portals" and, like the Christian Scientist, allows only constructive thoughts to enter. By exercising what he terms his will and imaging faculties, he believes that he can accomplish anything he desires to accomplish. The capacity is either within him and need only be released; or, if he believes that it comes from without, he feels that he need only place himself in the proper attitude of mind to receive it. The main point to him is that it is possible to him if he will but believe it, relax and permit demonstration to take place.

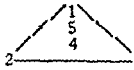
Relaxation in the case of treatment may involve a comparatively simple process consisting of substituting a calm state of mind for a more active one and placing the body in a resting position, or it may advance through the numerous states of lowered tension, varying from mere resting to a condition suggestive at least of a deep autohypnosis.

There are some New Thought centers in which the teaching includes elements of mysticism. The mystics make a practice of entering the silence, communing with the "cosmic mind," etc. In this state, which is described by them as a "superconscious" rather than an "unconscious" or a "subconscious" state, the mystic seeks to draw near to the source of all power, and through his contact to become imbued with its qualities. He believes that it makes him more powerful, wiser and less restricted by the limitations of time and space. In this state he has a "feeling of the presence" of God or the Infinite Power, and he returns to a conscious state with a sense of renewed energy which he believes he has gained from his contact with a higher consciousness than his own. In order to be worthy of this communion, he must live a holy life; and it is in respect to what constitutes this, as well as in the methods they advocate for "entering the silence," that teachers vary.

We have in New York an active Vedanta society, a Sufi center, teachers of the Yogi philosophy and various modifications of these and other similar systems.

One of the methods of entering the silence for the realization of anything, including health, as taught by Premel el Adaras, president of the Society of Transcendent Science, is as follows:

> Taking three candles, place them in the shape of a triangle thus:



> Now take a crystal (each individual requires a special crystal, according to his date of birth) and place it at 4. Next place some incense (this also must be individual) at 5.
>
> Have no other light except the candles and the glow of the burning incense. Sit with limbs folded as in the position indicated in likenesses of Buddha. Hold the arms rigidly flexed, forearms parallel with chest, hands outspread. Roll the tongue up and place it against the upper front teeth. Hold mouth shut, teeth one-eighth inch apart. This is to insure passing above the hypnotic into the "superconscious" state. Close the eyes. Now maintain this position until the hands are numb. Then look in the crystal and you will see yourself as you want to be, well, successful, happy or whatever your desire may be. After repeating this process for seven nights you will have tuned your mind in on Health, Wealth, Happiness, or whatever you desire. From thenceforth you need but relax and you will be attracted naturally to the desired end.

A variation of this treatment for health is to proceed with candles, crystal and incense as directed above.

> Instead of squatting on the floor or before the table on which they are placed, lie down totally relaxed on your bed. Drone slowly and distinctly until you fall asleep, the words Om, Mane, Padme, Hum, Om, Oum, taking care to allow the "m" sound to resound and cause a buzzing sensation directly above the nose. This will remove all symptoms and the patient will awaken refreshed and quite well.

This procedure is extreme, and less radical New Thought teaching does not as a rule promulgate such methods. Relaxation, however, figures largely in all treatments, and the use of formulas to be repeated under concentrated attention is an important element. Curing disease also is an active part of the work.

Although they do not assume the authority of parting the patient from his physician as do Christian Science practitioners, New Thought practitioners state that the patient is soon convinced of the greater efficacy of the new method and leaves his "crutches," i. e., medicine, eye-glasses if he wears them, etc., behind. It becomes quite unnecessary for the New Thought student to consult a physician. He feels that doing so interferes with his progress in his ability to help himself, or to be helped by New Thought, because it raises doubt in his mind.

At the last annual convention of the International New Thought Alliance, 10,000 persons were present. It is not possible, however, to obtain a reliable estimate of the large number of people connected with the New

Thought movement because it is so widely scattered. It has centers of one kind or another throughout the world. Its literature is very extensive. Ralph Waldo Trine's book, "In Tune with the Infinite," one of the best known New Thought books, has already been through 700 editions. The teachings are promulgated through magazines with wide circulation, lectures apparently always well attended, private courses, and individual instruction. Treatments are given by practitioners who are as a rule also teachers and lecturers. Meetings are for the most part held in hotel parlors or lecture halls. There are as yet no organized New Thought churches, housed in church edifices of their own.

Prominent among New Thought writers are Ralph Waldo Trine, Elizabeth and William Towne, Charles G. Leland, H. Emilie Cody, Kate Boehme, George Warton James, Gertrude Bradford and William Walker Atkinson, and there are others too numerous to mention. The literature includes almost every topic of successful living, with titles such as "How to Remake Yourself," "How to Cure Yourself," "Lessons on Truth," "You and Your Forces," "Worry, Hurry Cured," "Your Will Power, How to Develop It," and "Health and Wealth from Within."

DIVINE SCIENCE

Strictly speaking, while merely another type of New Thought, Divine Science stands out by itself. Its teaching is somewhat less complex, although there is a tendency for Divine healers to build up systems which are more or less individual and dependent on their personal convictions. The fundamental teachings are comparatively simple.

1. God is good and wishes only good for his creatures.
2. Disease, unhappiness, misfortune are of man's own making.
3. God will cure man and show him how to overcome all difficulties if man will but follow God, believing in his omniscence, omnipotence and omnipresence.

Treatment of a sufferer consists in persuading the individual of these facts, especially of raising in him the belief that God will cure him if he asks him to do so. This may be accomplished through conversation or reading of appropriate Scripture passages. When faith has been firmly established, the patient's state of expectancy is further enhanced by earnest prayer of an affirmative nature. This is not attempted until relaxation has been accomplished, nor until full cooperation on the part of the patient has been secured. Prayer is usually followed by "laying on of hands." This consists of placing the hands on the head of the patient.

To certain healers who believe themselves imbued with magnetic powers, this is a most important part of the treatment and must be carried out by a more or less elaborate technic with regard to position of the hands and attitude of the healer, in order that the flow of power from healer to patient may be facilitated. Others ridicule this idea.

New York has seen many such Divine healers, notable among them Francis Schlatter, Bradley Newell, John Alexander Dowie, and more recently James Moore Hickson. The Middle West still has several settlements established by Dowie. In New York are three active centers carrying on the work founded about 1919 by the late John Murray.

The followers of Murray believe that the mind forms the patterns for conditions in the physical body, and they guard their thoughts accordingly. They try to follow the teachings of Christ as interpreted by the founder of Divine Science, as the movement is known. In this way, they learn to think rightly and their welfare is accordingly influenced. They believe that they can dispense with medical help.

Those who have followed Mr. Murray in the leadership of the movement continue to teach and to heal. Besides work with individuals, they carry on daily public healing services. These consist of a short address by the leader, including a discussion of some appropriate Bible text, prayer and a "treatment." The leader reads or recites a given passage from the Scriptures or from Mr. Murray's writings, while the listeners close their eyes and relax. This is usually followed by affirmative prayer. The work is supported by free will offerings and the sale of Mr. Murray's numerous writings. These meetings are well attended, and the movement has hundreds of loyal, enthusiastic followers. The mention of Murray's name in other New Thought audiences frequently brings out considerable applause.

The best known Divine healer at present in this country is probably Mrs. Amy McPherson, who conducts services of a revivalistic nature and also does individual work. She is reputed as unusually successful in bringing relief to all kinds of sufferers, and is so popular that her followers have recently erected a large temple for her in Los Angeles, at the cost of $100,000. Mrs. McPherson claims "cures" in 80 per cent of the cases she treats.

THE TECHNIC OF MEDICATION

A SERIES OF ARTICLES ON THE METHODS OF PRESCRIBING AND PREPARING, THE INDICATIONS FOR, AND THE USES OF VARIOUS MEDICAMENTS *

BERNARD FANTUS, M.D.
Associate Clinical Professor of Medicine, Rush Medical College
CHICAGO

(Continued from page 1440)

Preservation of Aqueous Solutions.—While watery solutions of inorganic substances, or of organic substances with antiseptic properties, are not subject to change on keeping, there is quite a list of organic substances that are prone to fermentative or putrefactive decomposition when kept in aqueous solution without due precautions. Concentrated solutions of many of these substances are less prone to decomposition than are dilute solutions. Concentrated sugar solutions keep well, while dilute sugar solutions spoil readily. Weak solutions of many alkaloidal salts permit germ growth, while concentrated solutions may be easily kept germ free. This is one of the advantages of prescribing rather concentrated solutions to be diluted just before taking. Glucosidal principles in aqueous solution are very prone to decomposition.

Preservatives should be added only when they are unobjectionable from every standpoint. Among preserving agents, formaldehyde 0.05 per cent, has been found by Gabel[51] the most efficient, acting as it does in acid, alkaline and neutral solution. Benzoic acid, acting in 0.1 per cent solution, is superior to salicylic acid, of which 0.2 per cent is required; but either of them is efficient only in acid, and useless in alkaline medium. Alcohol preserves an acid drug preparation when present to the extent of 15 per cent; for alkaline and neutral liquid, 17.5 per cent alcohol is needed for preservation. Boric acid, chloroform and cinnamic acid have not been found efficient preservatives under the rather exacting conditions of Gabel's experiments. Glycerin, unless quite concentrated, is worthless as a preservative, 45 per cent being required in an alkaline medium; but even this much is insufficient in an acid or neutral medium.

---

* This is the twentieth of a series of articles on "The Technic of Medication." When completed the articles will be assembled in book form.

Sterilizing the solution and preserving it in sterile containers, such as ampules, is the most desirable method of preservation of solutions prone to bacterial decomposition, especially those that are to be used for *administration by injection.*

Vehicles.—In the art of prescribing, a good knowledge of vehicles is of the same importance as a liberal variety of spices and condiments in the art of cooking. Just as "we can live without art, but not so well," so we can get along without artistic perfection of our medicaments, but by no means so well. Our formularies offer us a choice among aromatic waters, spirits and tinctures, as well as among sweet preparations, such as syrups and elixirs.

As the choice of the proper vehicle is determined in the first place by the solubility of the active ingredients, it will be most helpful to arrange the vehicles, in accordance with their solvent action, into (1) aqueous and (2) alcoholic vehicles.

Aqueous Vehicles: The official waters are aqueous solutions of volatile substances.[52] Two very dissimilar classes of preparations come under this heading: the aromatic waters and the chemical waters, such as ammonia water.

Only the aromatic waters concern us here. They are saturated solutions of volatile oils and analogous substances. As volatile oils are only slightly soluble in water, the aromatic waters are weak preparations. The quantity that dissolves is just large enough to give these waters a pleasant flavor without imparting to them noticeable therapeutic properties. Hence their dose is large, ranging from 4 to 16 cc. One may use, as pleasant vehicles, anise water, fennel water, orange flower water, cinnamon water, peppermint water and rose water. The last named seems to be more suitable for external rather than for internal use. Chloroform water is really quite pleasantly flavored, of slightly sweetish taste, and has preservative powers which make it desirable for solutions that do not keep well.

Among the sweet aqueous vehicles, most prominent are the syrups, which are nearly saturated solutions of sucrose in aqueous liquids. Their especial value lies in pleasant taste of sugar and its action as a preservative. While dilute solutions of sugar ferment quickly unless preserved by special means, a fully saturated solution is not only quite stable but even capable of preserving other substances from fermentation, probably because sugar by its great affinity for water renders unavailable the moisture necessary for the development of microorganisms. Sugar forms, furthermore, an excellent preservative for certain unstable chemicals, such as hydriodic acid, ferrous iodide and hypophosphites, inhibiting chemical change probably by reason of its own chemical sluggishness. While some of the official syrups, as the syrups of the chemicals mentioned above, have an intrinsic medicinal action (medicated syrups), the majority of them are mere flavoring vehicles. The flavoring syrups, generally administered in doses of a teaspoonful—though much more might be given—are too thick and too sweet to be given undiluted; but the dilution should be ordered just before taking rather than in the prescription itself, for diluted syrups spoil readily on keeping, unless antiseptic ingredients are present. Interfering with a child's appetite and digestion by frequent dosing with heavy syrup should, of course, be avoided, especially in the case of ill nourished and feeble children, whose recovery may depend more on improved nutrition than on any medicament.

The official syrups named below are used in pleasant medication, and it is well to be familiar with all of them; for, just as variety of flavoring is aimed at in cooking, so is it well to aim at such variety in medication. If most of a physician's medicines look and taste nearly alike, as they easily may when he uses the same flavoring vehicle, patients may come to suspect that he uses the same medicine for all kinds of ills. When several members of a household require different medicaments, it is well to make distinction easy between them by marked divergence in color, flavor and taste. The syrups referred to above are:

Syrup, sometimes, though unnecessarily, also called simple syrup.

Syrup of citric acid (lemon syrup), which has an acid reaction due to citric acid (1 per cent) and hence is incompatible with alkali carbonates.

Syrup of orange, which also contains citric acid (0.5 per cent).

Syrup of orange flowers.
Syrup of pine tar.
Syrup of wild cherry.
Compound syrup of sarsaparilla.
Syrup of tolu.
Syrup of ginger.

To this list the following contributions of the National Formulary might be advantageously added:

Compound syrup of asarum (wild ginger).
Syrup of cacao (chocolate syrup).
Syrup of cinnamon.
Syrup of glycyrrhiza.
Aromatic syrup of eriodictyon (yerba santa).
Syrup of raspberry.
Syrup of thyme.

Among these, the syrups of citric acid, of orange and of raspberry might be noted most especially as pleasant vehicles for salines, the syrup of wild cherry as a corrective for sour tastes, and the syrups of cacao and glycyrrhiza, and the compound syrup of eriodictyon as the most suitable of the syrup vehicles for bitter drugs. One must beware of straining excessively the disguising values of syrups, most especially for the last named purpose: for the bitter sweet taste is repulsive to most of us. Thus, while quinine (alkaloid) or quinine ethyl carbonate (euquinine) in children's dosage may well be given in any one of the last mentioned syrups, it would be folly to try to disguise the taste of strychnine by means of them. Unusual flavors, like those of the compound syrup of asarum or of the syrup of thyme, are sometimes relished when the old familiar flavor of licorice or tar might seem flat and stale.

---

[51] Gabel, L. F.: Preservatives in Pharmaceutical Preparations, J. Am. Pharm. A. **10:** 767 (Oct.) 1921.

[52] In contradistinction to the official solutions, which are aqueous solutions of nonvolatile substances, excepting syrups, infusions and decoctions, which naturally form distinctive classes.

The syrups are freely mixable with water and aqueous liquids, but, if added in concentrated form to strong alcoholic liquids, the sugar is precipitated or gradually crystallizes out of solution, as it is much less soluble in alcohol than in water. Being concentrated solutions, syrups will dissolve only a small quantity of other substances. If it is necessary to dissolve a large quantity, a certain amount of water will have to be added.

For diabetic patients and others for whom the prescribing of sugar would be undesirable, or if its fermentation must be avoided, gluside (saccharin) or soluble gluside (soluble saccharin) might be employed in quantities not exceeding 1 part per 2,000; otherwise it becomes disagreeable. Popular opinion to the contrary notwithstanding, gluside is perfectly harmless in any quantity that might be employed for sweetening of food or medicine.

Alcoholic Vehicles: Aromatic spirits and tinctures are chiefly used for the flavoring of strongly alcoholic liquids. All of them are incompatible with water. Among them may be mentioned:

Spirit of anise.
Compound spirit of orange.
Spirit of cinnamon.
Spirit of peppermint.
Spirit of spearmint.
Tincture of lemon
Tincture of tolu
Tincture of ginger.

These are rather strong (average, 10 per cent) alcoic solutions, the average dose of which is given as nging between 1 and 2 cc. Even one tenth of this suffices for the flavoring of alcoholic medicaments. The spirit of lavender and the compound tincture of lavender are perhaps better suited for flavoring external applications than medicament for internal use, though the latter is the traditional flavoring and coloring ingredient of the solution of potassium arsenite (Fowler's solution).

The aromatic tinctures are of interest because they offer eligible vehicles for alcohol soluble medicaments, especially those of bitter taste, which are not improved by sweetening. The best one among those made with strong alcohol as a menstruum is the tincture of sweet orange peel. In connection with it and the aromatic spirits we must remember that, when used in any considerable proportion, they are incompatible with water and even with diluted alcohol.

Tincture of cardamom and compound tincture of cardamom are made with diluted alcohol (50 per cent) and may be remembered as useful diluent and flavoring vehicles for tinctures made with mixtures of nearly equal quantities of alcohol and water. The dose of these aromatic tinctures is a teaspoonful. These, as well as all other strongly alcoholic liquids, should be freely diluted just before taking.

Elixirs are aromatic sweetened alcoholic preparations in which medicament may be dissolved. The first object aimed at in the modern elixir is an agreeable flavor. By means of it, the taste of nauseous medicines may often be rendered less disagreeable. They are especially useful as vehicles for hydro-alcoholic preparations, such as tinctures and fluidextracts, if their alcohol content is properly adjusted. There are two elixirs official in the U. S. P., aromatic elixir and elixir of glycyrrhiza, the latter of which is merely 12.5 per cent of fluidextract of glycyrrhiza added to aromatic elixir. The red aromatic elixir of the N. F. is aromatic elixir colored a beautiful red by 2 : 1,000 of cudbear. It must be remembered that these elixirs containing from 20 to 25 per cent of alcohol are as strong in alcohol as the strongest sherry wine, that even teaspoonful doses may be intoxicating to infants, and that their long continued use in liberal quantities may lead to the alcohol habit. Hence, unless medicated, these are classed among the intoxicating beverages by the National Prohibition Act, and cannot be prescribed except by complying with all its provisions.

The National Formulary affords a number of elegant vehicles of much lower alcohol content than the U. S. P. elixirs. The following elixirs contain only from 5 to 10 per cent alcohol—merely enough for solution and preservation—and, properly diluted, are admirable vehicles even for administration to children:

Aqueous elixir of glycyrrhiza—this is a good vehicle especially for salines, such as bromide and iodide.
Compound elixir of almond, especially useful for sour medicines, with which it gives the "cherry phosphate" flavor.
Elixir of anise.
Compound elixir of cardamom.
Compound elixir of vanilla.

It must be admitted that the physician experiences considerable difficulty in adjusting the alcoholic strength of his vehicles to yield clear and permanent solutions with the various medicinal fluidextracts and tinctures, as it is difficult for him to bear always in his mind the exact alcoholic strength of the menstruums. This difficulty could be overcome by the use of "iso-alcoholic elixir," as suggested by Fantus and Snow,[53] an elixir automatically adjusted by the pharmacist so as to have an alcoholic strength just sufficient to dissolve the medicament for which the elixir is to serve as a vehicle. The aromatic elixir of the present U. S. Pharmacopeia contains approximately 25 per cent alcohol, which is sometimes too much and sometimes not enough. Thus, if this elixir is to serve as a vehicle for sodium bromide, potassium acetate or sodium salicylate, no such amount as 25 per cent alcohol is required or desirable; alcohol, be it remembered, actually increasing the taste impression produced by these substances. If, on the other hand, it is to be used as a diluent for fluidextract of cannabis or fluidextract of buchu, it is decidedly deficient in alcohol and, in both instances, turbid unsightly mixtures result. Indeed, whenever there is a marked discrepancy between the alcohol strength of elixir and medicating preparation, precipitates occur, which in some cases, as, with tinctures of digitalis, veratrum viride, aconite, nux vomica, colchicum and lobelia, are liable to be toxic and dangerous. To enable the pharmacist to dispense iso-alcoholic elixir, two basic aromatic elixirs are required: first, an aqueous elixir containing approximately 5 per cent alcohol;

---

[53] Fantus, Bernard; and Snow, C. M.: J. Am. Pharm. A. **10**: 277 (April) 1920.

and, secondly, an alcoholic elixir containing 95 per cent alcohol. The following formulas are proposed for these:

Aqueous Elixir

Compound spirit of orange	10 cc.
Alcohol	50 cc.
Syrup	375 cc.
Glycerin	200 cc.
Distilled water	to make 1,000 cc.

Purified talc is used for clarification.

Alcoholic Elixir

Compound spirit of orange	5 cc
Gluside	3 Gm.
Glycerin	200 cc.
Alcohol	to make 1,000 cc.

These two are mixable with each other in all required proportions.

If the physician prescribes "iso-alcoholic elixir," the pharmacist who is familiar with these preparations would take care of the proper alcoholic strength of the vehicle by using the aqueous and the alcoholic elixirs in the proportion in which water and alcohol exist in the menstruum of the active preparation, or is required for the making of a solution. This he could easily do with the help of his reference books. Incidentally, it might be noted that the alcoholic elixir, as it contains gluside (saccharin) instead of sugar, might be used as a pleasant alcoholic vehicle for medicaments intended for the diabetic patient. The aqueous elixir, containing only about 5 per cent alcohol, might also be employed as an additional elegant vehicle for water-soluble medicaments for children.

The use, as vehicles, of the elixir of pepsin and of the compound elixir of pepsin and rennin, elixir of caroid, and the like, has no scientific foundation whatever, as the digestive ferments are practically never absent from the stomach in cases of dyspepsia. It is difficult to see how the presence of these ferments in a medicament could make it more acceptable to a stomach that has an abundance of ferments, as it is well known that a slight increase in the amount of ferment does not measurably increase digestive activity. The practice is, no doubt, a survival of the day—not so long past—when the digestive ferments were hailed, even in scientific circles, as a panacea for digestive disorders. Commercial interests have been and are still at work to keep the fallacy alive. *It is not to be denied that* these elixirs are pleasant vehicles but they would be just as pleasant, just as efficient, and less expensive without the digestive ferments.

(To be continued)

Activities in the Athenian Program of Physical Education.—Games and gymnastics in Athens seem to have included most of the forms practiced in later life—running, the broad jump with and without weights in the hands, throwing the javelin and the discus for distance, and, above all, wrestling, besides the rudiments of boxing, and a form of the pancratium, a struggle which combined certain features of both boxing and wrestling with others of its own. Mention is also made of simple exercises to develop correct carriage and a graceful step in walking, and it is said that the art of swimming was early acquired, and that games, especially those in which the ball was used, were by no means forgotten. Dancing, at least in its more advanced forms, was not a regular subject of instruction at Athens, but was left to choral bands which received special training for their appearance before the public on festal occasions.—Leonard: History of Physical Education, p. 222.

ACTIVE "CORRESPONDENCE" DIPLOMA MILLS

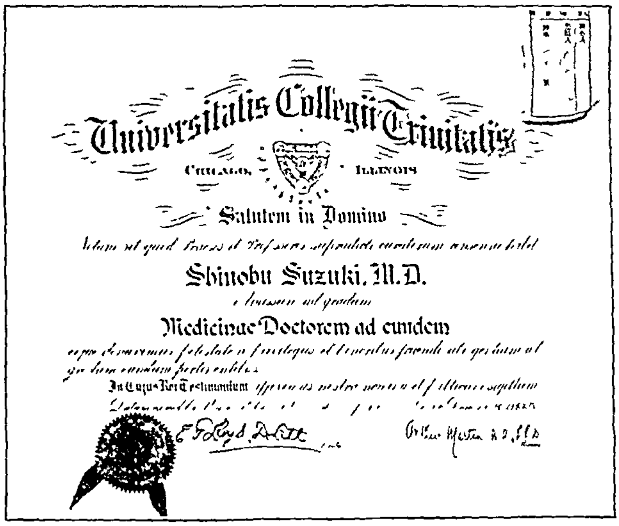
REPORT OF THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

From time to time diploma mill scandals have aroused the public and physicians to the dangers of the lack of suitable control of educational institutions. The laxness of laws permits the easy establishment of schools and colleges of all kinds in many states, and the difficulty of verifying graduation and diplomas permits unqualified men to secure credentials to which they are in no manner entitled.

The report that follows indicates the difficult procedure sometimes necessary to prevent unwarranted use of such diplomas, and exposes the nature of several closely related diploma mills.

The University of Trinity College

Hardly a month passes but some new "university" with a high sounding title is found to be filling the mails with follow-up letters or issuing diplomas after the flimsiest pretenses of their having been earned. The latest instance, evidently, is the "University of Trinity College" or, latinized, the "Universitatis Collegii Trinitatis." Nothing was known regarding this institution until photostat copies of diplomas issued to two students in Japan were received from the editor of the *Japan Medical World*. These diplomas, indeed, looked genuine, literally bedecked as they were with official signatures and seals of an imposing nature. The signature of the president of the "university" had been certified to by a notary public of Chicago; the notary's signature by a county clerk in Illinois, and each subsequent signature in turn certified to, evidently, by higher American and Japanese officials. Both of these diplomas were "ad eundem" degrees issued, respectively, to Shinobu Suzuki and Hanhito Otake by the University of Trinity College. A third diploma accompanying those of the University of Trinity College was a degree in medicine also "ad eundem" issued by Lincoln-Jefferson University to one Ribeji Hagibani. The three diplomas are



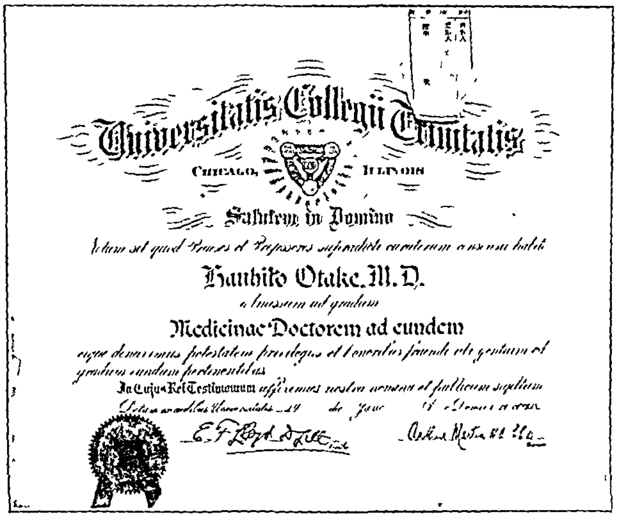
Universitatis Collegii Trinitatis
Chicago, Illinois
Salutem in Domino
Shinobu Suzuki, M.D.
Medicinae Doctorem ad eundem
In Cujus Rei Testimonium

Fig. 1.—Although this diploma is signed by two persons unidentified in other literature of the university, it was accompanied by an affidavit issued in the name and under the seal of the "University of Trinity College," signed by "A. W. Slade, D.D., LL.D.," as "President of the University and Board of Trustees." (See upper portion of figure 4.) In this affidavit the name of Shinobu Suzuki was not followed by the "M.D."

reproduced herewith. Meanwhile, we are informed that the three Japanese who obtained these irregular medical diplomas have been discredited in Japan.

A MEMBER OF THE LINCOLN-JEFFERSON BROOD

An investigation was instituted immediately to ascertain the origin of the so-called University of Trinity College. Strangely, this great institution appears to have been overlooked by all the recognized standardizing agencies which prepare lists of approved colleges and universities. A careful search of the Chicago telephone directories for the last five years also revealed no institution by that name. It soon became evident, however, that it was another member of the Lincoln-Jefferson family.



Universitatis Collegii Trinitatis
Chicago, Illinois
Salutem in Domino
Hanbito Otake. M.D.
Medicinae Doctorem ad eundem
In Cujus Rei Testimonium

Fig. 2.—Although this diploma is signed by two persons unidentified in other literature of the university, it was accompanied by an affidavit issued in the name and under the seal of the "University of Trinity College," signed by "A. W. Slade, D.D., LL.D.," as "President of the University and Board of Trustees." (See upper portion of figure 4.)

Photostat copies of the certification of the three diplomas referred to solved the problem. The diploma issued by Lincoln-Jefferson was certified to by "A. W. Slade, D.D., LL.D., as president of the University and of the Board of Trustees," and the certificate was stamped with the seal of Lincoln-Jefferson University.

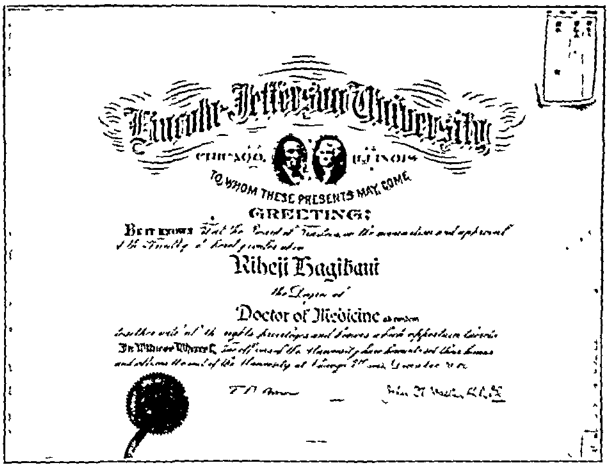
The diplomas of the University of Trinity College were also certified to by "A. W. Slade, D.D., LL.D., President of the University and of the Board of Trustees." The latter, however, as shown in figure 4, were stamped with the seal of the "Universitatis Collegii Trinitatis." These disclosures show that the University of Trinity College is conducted by the same individuals who are responsible for the Lincoln-Jefferson University, even though the diplomas of the two institutions bear different signatures.

A letter from the secretary of state of Illinois shows the University of Trinity College was legally chartered, having been incorporated in Illinois in 1921 under the "not for profit" act. The address given was room 718, 155 North Clark Street, Chicago—a different address from that of Lincoln-Jefferson University, but its board of directors and incorporators were F. J. B. Walker, 1006 Michigan Avenue, LaPorte, Ind., A. L. Walker, 1006 Michigan Avenue, Laporte, Ind., and E. C. Ravenscroft, 127 North Dearborn Street, Chicago—persons closely identified with the latter institution.

According to circulars of the Lincoln-Jefferson University in the files of the American Medical Association, "Rev. John F. B. Walker, Ph.D., D.D., LL.D., F.R.G.S.," is given as "a perpetual member of the Board of Trustees" and for six years president of the Lincoln-Jefferson University. "E. C. Ravenscroft, Ph.D., J.D., D.C.L.," was its former secretary and is now a member of the board of trustees. As president of Lincoln-Jefferson, "Rev." Walker signs himself as "John F. B. Walker, Ph.D., D.Sc." At LaPorte, Ind., he is known as Rev. Dr. F. J. Barwell-Walker and, we are informed, is the rector of the Episcopal church at that place. This church is located at 1002 Michigan Avenue, and the rectory is at 1006 Michigan Avenue, LaPorte, Ind.—the same address that appears in the articles of incorporation of the University of Trinity College, although on the latter the initials are reversed, reading, "F. J. B. Walker." There may be definite reasons why in the signatures the initials are occasionally twisted around. The "Rev." A. W. Slade, D.D., LL.D., is reported also to be the rector of the local Episcopal church at Valparaiso, Ind. One wonders whether the degrees paraded by these two "reverends" are the products of their own mills; also whether these are not two more cases of "Dr. Jekyll and Mr. Hyde."

HEADQUARTERS OF THE LINCOLN-JEFFERSON UNIVERSITY

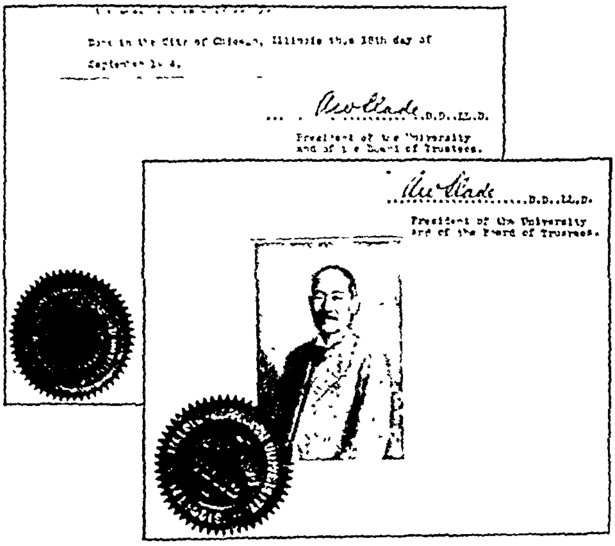
Interest in the offspring of the Lincoln-Jefferson University led to an investigation of the addresses given for it and for the University of Trinity College. Room 718, 155 North Clark Street, Chicago, the address of the latter, proved to be occupied by a group of architects who knew nothing of such an institution. The entire university had vanished or moved to parts unknown to them. Evidence revealed a connection between University of Trinity College and Lincoln-Jefferson, so that a visit was made to the latter's address given in the telephone directory. The Lincoln-Jefferson University occupies what it is pleased to call its "main headquarters"—a room on the eleventh floor of an office building in Chicago's business district. The investigator found that the entire university, including all it had in the way of laboratories, botanical gardens, libraries, lecture rooms and other equipment—such as are usually required to make up a reputable university—occupied a space not more than fourteen square feet, and space was still left for the University of Trinity College. These fourteen square feet were honored as the site, therefore, of two great universities. Possibly this is why the space had been divided into two rooms.



Lincoln-Jefferson University
Chicago, Illinois
To Whom These Presents May Come
GREETING:
Be it known
Riheji Hagibani
Doctor of Medicine
In Witness Whereof

Fig. 3.—Note that this diploma is signed by "John F. B. Walker, Ph.D., D.Sc., President," whose name stands first among the officers and faculty of the Lincoln-Jefferson University. It was accompanied also by an affidavit bearing the seal of the Lincoln-Jefferson University and signed by "A. W. Slade, D.D., LL.D., President of the University and Board of Trustees." See lower portion of figure 4.

The smaller room, apparently the holy of holies, bore a sign "Private." The college furniture and equipment in the larger room consisted of (*a*) one desk of very ordinary appearance; (*b*) one bench, which would seat two or possibly three "students," and (*c*) two or three ordinary chairs. The entire visible personnel was embodied in a woman of thirty-five or forty summers who informed our investigator that a "Dr." Slade in Valparaiso, Ind., would be glad to answer any questions submitted to him. The work, she said, was carried on by correspondence and all manuscripts were forwarded to Dr. Slade of Valparaiso and Dr. Walker of LaPorte, Ind., to whom she referred as "two English ministers" and also as "the head men on the faculty." When questioned as to whether or not medical courses were given by correspondence, she said rather hesitatingly that she thought "such work isn't given." Later she remembered that the faculty did give preliminary work in medicine.



Done in the City of Chicago, Illinois this 18th day of September 19 4.

A W Slade ..D.D., LL.D.
President of the University and of the Board of Trustees.

A W Slade ..D.D., LL.D.
President of the University and of the Board of Trustees.

Fig. 4.—These show the signatures and seals on the affidavits which accompanied the diplomas shown in figures 1 and 3. Note that both are signed alike by "A. W. Slade, D.D., LL.D., President of the University and the Board of Trustees," although one bears the seal of the University of Trinity College, the other the seal of the Lincoln-Jefferson University (names on seals Latinized).

STATEMENTS IN CATALOGUE

In a catalogue obtained on this visit it is stated that the Lincoln-Jefferson University and the University of Trinity College are "affiliated" and that the charter of the latter came "under the control of the Lincoln-Jefferson University in 1923." A report from the secretary of state of Illinois regarding the University of Trinity College, however, shows that it was chartered in 1921 by practically the same group that was then in control of the Lincoln-Jefferson University.

Another statement in the catalogue is that courses "are offered in the University of Trinity College under rather less strict (?) regulations than are in force with the Lincoln-Jefferson University," and that any one "holding Lincoln-Jefferson University degrees may duplicate those degrees from Trinity College by payment of the regular ad eundem degree fees."

In view of the three diplomas reproduced in this article, the statement published in the catalogue "that M.D. . . . degrees are not offered *by any reputable* school of correspondence work" (italics ours) and "we are not prepared to offer courses leading to these degrees," is sadly amusing. In a letter to the California board, John F. B. Walker states: "No medical degree has ever been conferred during my time with the Lincoln-Jefferson University for nonresident work." Nevertheless, note the degree from Lincoln-Jefferson University reproduced in this article, which was evidently signed by John F B Walker himself! Probably the fact that the American Medical Association has this part of the diploma mill field pretty well safeguarded so far as North America is concerned explains the sentence.

The willingness of this school to deceive the public is indicated by the statement in its catalogue that "all diplomas are issued without mention that any part of the work was taken by correspondence." In other words, let the public look on them as evidences of honest-to-goodness study, if they are foolish enough to do so!

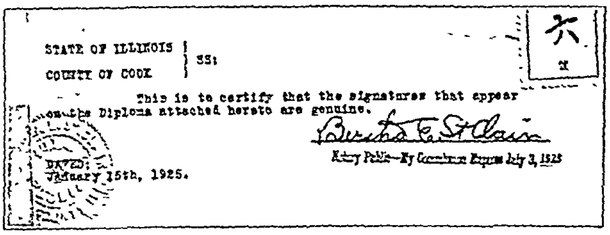
ARE THESE DIPLOMAS RECOGNIZED?

It is amusing to note at the back of the bulletin of the Lincoln-Jefferson University that one of "A Few 'Dont's' to Remember" reads "Don't be disappointed if some resident school does not give you reasonable credit for your work with us. It is not our fault. You will be suffering for the faults of correspondence schools in the past unless it happens to be simply stubbornness or 'swelled head.'" As a matter of fact, students of this university are "disappointed," no doubt, if they attempt to transfer their credits to any recognized institution

The diplomas issued by these institutions are of so suspicious a character as to make them unworthy of recognition by reputable educational agencies or institutions. The officers of these mills, meanwhile, are carrying on their traffic in spurious degrees at the same time that they are hiding under their ministerial garbs as purveyors of truth and sanctity! According to the strings of degrees following their names, the "Rev. A. W. Slade, M.A., D.D., LL.D.," and the "Rev. John F. B. Walker, Ph.D., D.D., LL.D., F.R.G.S.," might be viewed as paragons of erudition, were it not for the suspicion that all these degrees were obtained, probably without the expenditure of either time or money, from the same mills which are furnishing degrees so liberally to others at so much per.

The American University—Another Member of the Brood

The Lincoln-Jefferson University is shown to be closely related with a third institution, a so-called "American University" of Highland Park, Los Angeles, the incorporators of which, again, are Francis J. B. Walker, LaPorte, Ind., and E. C. Ravenscroft, Chicago. In a communication to the California State Board of Medical Examiners, Walker admitted that he "had agreed to hold the honorary position of chancellor of the American University and to act as dean of its theological department . . . until Ravenscroft could get things organized." The files of the California board show that the American University was incorporated in that state, April 11, 1921, but the first affidavit of the corporation papers were executed in Cook County, Ill., March 21, 1921. There is an "American University" incorporated in Illinois, but evidently by an entirely different group of individuals. Possibly it is in affiliation. The latter is a mail-order, correspondence affair of the most flagrant type and is conducting a large



STATE OF ILLINOIS }

DATED:
January 15th, 1925.

Fig. 5.—This shows the signature and seal of the notary public who certified to the signatures of "A. W. Slade, D.D., LL.D." on the affidavits which accompanied the diplomas shown in figures 1, 2 and 3. Rev. Dr. Slade's signatures are shown in figure 4.

business in the issuing of diplomas, the main requisite evidently being the collection of the fees! A glance at the incorporation papers of the California institution, reproduced below, reveals no lack of versatility on the part of the "university"—quite consistent with the character of the "American University" of Illinois. Besides the numerous "colleges" listed which confer degrees, note also that the university reserves the privilege to add "any other colleges, schools or seminaries or departments that circumstances may require" Indeed, degrees of any kind seem available for the asking (and, of course, the payment of the required fee!) from this group of institutions which, although dignified by the title "university," on investigation were found to lack the buildings, grounds, laboratories, libraries and other things deemed essential by all bona fide and reputable universities!

American University

Incorporation No 94945, Filed April 11, 1921

The purposes —To provide, either in residence or by correspondence courses of instruction leading to all degrees usually granted by universities and colleges in the College of Liberal Arts, the College of Science, the College of Law, the College of Pharmacy, the College of Political and Social Sciences and Commerce, the College of Education and Normal Development, the College of Applied Science, the College of Divinity of Theological School or Seminary, the College of Fine Arts, the College of Agriculture, the College of Music, the College of Engineering, the Graduate College, the Grammer School, the High School or Academy and any other colleges, schools or seminaries or Departments that circumstances may require On the completion of such courses to issue appropriate diplomas To confer ad eundum and honorary degrees in all departments as may be deemed desirable This corporation reserves the right to establish branches of this University in any State of the Union and in all parts of the world.

The place of business is given as Los Angeles, and the "Directors and Trustees" are named as follows:

Francis J B Walker, La Porte, Ind
E C Ravenscroft, Chicago, Ill (Temporarily)
S C Ravenscroft, 454 West End Ave 56, Los Angeles
A M Ravenscroft, 454 West End Ave 56, Los Angeles
L M Ravenscroft, 454 West End Ave. 56, Los Angeles

THE "AMERICAN UNIVERSITY'S" HEADQUARTERS

A visit to the main office and headquarters of the American University revealed a small upstairs room at 5636 Pasadena Avenue, Highland Park, Los Angeles, which was not only the "office," but also the living and sleeping quarters of "Dean" Ravenscroft The complete furnishings of the "university" were enumerated as a dilapidated bed, an aged desk and a couple of chairs. From subsequent inquiry and an abundance of information on file, this equipment appears to harmonize perfectly with the character of this university.

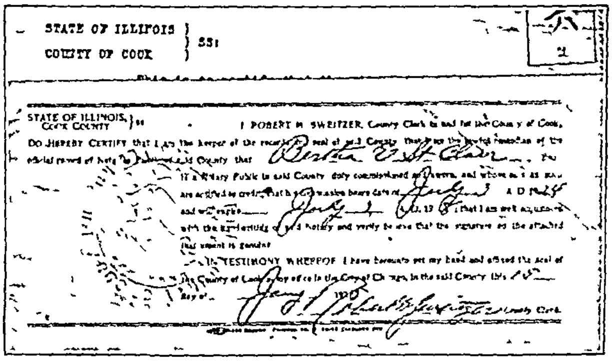
During the interview, the "dean" used the pronoun "we" in discussing the affairs of the university. When asked who the "we" included, he admitted it was just himself, because the word "we" sounded better. A bulletin of the American University showed that Rev George M. Kelly was president; that Samson C. Ravenscroft was secretary, and that George T Mills was treasurer. The "dean" stated that President Kelly was his cousin and that he was a preacher living in West Virginia, but refused to reveal his mail address, saying, "You know how relatives are, they go back on you when you get in trouble" "Samson C Ravenscroft is my brother," said the dean. "He tried the real estate business for awhile, but of late has been working as a house painter." He said that George T. Mills, the treasurer, was his cousin and that he lived in Santa Monica, Calif. Dean Ravenscroft stated that Irving I Jacobs, the "Dean of Pharmacy," resided in New Haven, Conn.; the "Dean of the Business College" at Miles City, Mont.; the "Dean of the Teachers' College" at Washington, D C ; while the "Dean of the College of Liberal Arts" held forth at Peru, Ind, and two other members of the faculty lived somewhere in England, their exact address being unknown.

The "dean" admitted that he was connected formerly with a correspondence school in Chicago, and that some one in that city occasionally sent him a list of names of prospective students to whom he would send the university's letters and literature. This alleged correspondence school offers to confer doctor degrees as well as the title of professor and to issue diplomas to accountants.

Reports show that agents of the American University have openly advertised its degrees in England, Venice, India and Japan A communication from Japan alleges that the American University, as well as the University of Trinity College and the Lincoln-Jefferson University, are offering correspondence degrees and selling diplomas in liberal arts, law, medicine and pharmacy to Japanese, Indians and Chinese at a good price.

DEGREES OF ALL VARIETIES—OTHERS FOR THE ASKING

The announcement of the Lincoln-Jefferson University[1] states that in 1917 "things could hardly have been worse" inasmuch as "there were few students and no funds." Conditions certainly "have changed" in regard to students (or graduates) and regarding funds also, no doubt. In slightly more than two years after Sept. 16, 1920, 536 degrees are listed as having been issued; there were thirty-eight different varieties and in twenty different subjects, besides academic diplomas and certificates in shorthand and typewriting. Titles of "professor" of this, that or the other subject have also been issued. The statement, in capital letters, appears that *"If you do not find what you want . . . write to the president."* In the charter of the American University of Los Angeles, also, after naming eighteen different schools and colleges, it is provided that "any other colleges, schools or seminaries or departments that circumstances may require" may be opened by this university. Right is reserved also "to establish branches of this university in any state of the Union *and in all parts of the world*" [Italics ours.—Ed.]



STATE OF ILLINOIS }
} SS:
COUNTY OF COOK }

STATE OF ILLINOIS, COOK COUNTY } ss I ROBERT M. SWEITZER, County Clerk in and for the County of Cook,

DO HEREBY CERTIFY

IN TESTIMONY WHEREOF

Fig 6—This is a photograph of the certification by the county clerk of Cook County, Ill, to the signature of the notary public who, in turn, certified to the signature of the "President of the University and Board of Trustees," who certified to the three diplomas reproduced in figures 1, 2 and 3—sort of a "House-that Jack Built" affair! The county clerk's signature was also supposed to be certified to by the signature and seal of the Japanese consul, and the latter's signature was certified to by the signature and seal of the Japanese ambassador—or some other higher Japanese official Thus the three diplomas, which were of little if any value educationally, reached Japan literally bedecked with official signatures and seals—if not also with ribbons!

ADVERTISING DIPLOMAS ABROAD

The good name of American education in foreign countries has suffered greatly from the activities of the agents of such "legally chartered" correspondence mills, which are really without equipment and standards but are always ready with degree conferring diplomas—elaborately signed and sealed but which educationally are of doubtful value—for which they are always ready to receive money. Most American educators have little knowledge of these invisible, underworld, mail-order affairs, just as respectable citizens know only through the newspapers of the activities of criminals and the passing of counterfeit money. Very few Chicago people, indeed, have any idea that such great (?) institutions as the "Lincoln-Jefferson University" or the "University of Trinity College" are located in the very heart of the city. These organizations, in fact, seldom advertise their wares in American newspapers, but prefer to work through the mails and through agents. They are inclined, evidently, to favor advertisement in countries far distant from American university centers; such as in India, Italy, South America and Cuba, and especially among the minor clergy whose vanity tempts them to secure some degree in theology or divinity—of which this university is ready to furnish some six or seven varieties.

---

[1] Vol V, New Series, no 1

ACTIVITIES IN ITALY

In 1924, in Venice, one Prof. Dr. Serge Boris Dietrich, associated with two such institutions in selling "American degrees" in Italy, was imprisoned for one year and three months. The American consul, in reporting to the Department of State the trial and conviction of the man, said:

> The press of Venice gave wide publicity to the trial, as the testimony regarding the sale of the diplomas, titles and degrees furnished material therefor. American universities in general, in fact, all American institutions, came in for their ridicule; so that the prestige of American education has suffered somewhat of a shock in Italy at present. The inability of foreigners to differentiate between real universities and such universities as the Oriental University of Washington, D. C., and the American University of Los Angeles, Calif. (which were frequently mentioned in the testimony, owing to Dietrich's having represented them), made it seem natural that the inferiority of American institutions of learning should appear generally manifest to all who heard the testimony or read the press notices. As previously pointed out by this consulate in several of its dispatches of last year, *present conditions, whereby diploma mills of this sort are permitted to exist for the foreign market in degrees of American origin, militate against the entire education system of the United States and its prestige abroad.*[2] [Italics ours.—Ed.]

ARE THESE "BIRDS OF THE SAME FEATHER"?

From the foregoing, as well as other evidence, it is apparent that Prof. Dr. Serge Dietrich—sometimes given as Sergei Boris Dietrich—was the acting agent for both the American University of Los Angeles, Calif., and the Oriental University of Washington, D. C. As noted elsewhere, the charter of the latter institution was revoked, and on Jan. 9, 1926, its president, "Bishop" Helmuth P. Holler, was convicted on a charge of conspiracy for the purpose of making fraudulent use of the mails.

EVASION OF IMMIGRATION LAW

There is a suspicion that this traffic in diplomas is also aiding foreigners to evade the American immigration laws which permit the entrance of professional men from foreign countries over and above that country's annual immigration quota. It is not improbable that possessors of diplomas issued by phantom universities such as the "American University," as their character might be unknown to the immigration officers, would be permitted to enter the United States.

Diploma Traffic in India

Those conducting the Lincoln-Jefferson University and the other members of its brood are evidently doing a land office business in diploma selling in British India. Here again, as in Italy, one of the native agents was a graduate and an agent of the now defunct[3] Oriental University. This agent, Dr. Heramba Nath Chatterjee, openly advertised in the newspapers to the effect that American degrees in almost every subject known to educational bodies could be "arranged" by the "authorized board."

Chatterjee was said to have been also the agent of "The International University of the U. S. A.," which, by "affiliation," is apparently another member of the Lincoln-Jefferson brood. He is said to have occupied a rented room in Calcutta, where he acted as dean and entire faculty of several irregular "temples" and "colleges," including a bogus "Washington Medical College" which he claimed was "affiliated" with an American university—evidently the Lincoln-Jefferson University, of which Chatterjee appears as agent.

ANOTHER AGENT AND FACULTY MEMBER

Dr. Satish Chandra Banerjee, another local representative of the Lincoln-Jefferson University in India, is named in the Lincoln-Jefferson announcements as having been granted an M.D. degree and also as a member of its "faculty and advisory board." According to a report,[4] this agent openly published items in lay newspapers declaring that the Lincoln-Jefferson University "was chartered in Illinois"; "was recognized by the United States government"; "had no correspondence courses in medicine"; "did not grant honorary degrees." and that "the work of the Lincoln-Jefferson University was satisfactory to the 'Indian State Board.'" An investigation, however, brought out the facts that (*a*) "legal charters" in the United States meant very little because any one could easily obtain them and that the lowest type of diploma mills, including those closed by the courts, always have been "legally chartered"; (*b*) not only is the Lincoln-Jefferson University not recognized by the government of the United States, but its name does not appear in the list of recognized universities published by the United States Bureau of Education; (*c*) although the Lincoln-Jefferson University claims to have no correspondence course in medicine, the report of the Secretary of State of the United States says that all the work of the Lincoln-Jefferson University [whatever it may or may not consist of] is "conducted by correspondence"; (*d*) the agent's statement that "it does not grant honorary degrees" is contradicted by the Lincoln-Jefferson University in a letter stating: "We are not giving any course in medicine at all, nor do we grant medical degrees *excepting ad eundem and honorary*" [italics ours; honorary and ad eundem degrees are just as pretentious as earned degrees and will as readily deceive a credulous public.—Ed.]; (*e*) the Indian government has no "state board" such as was declared to be "satisfied with the work of the Lincoln-Jefferson University."

NO BRITISH RECOGNITION

The opinion of the General Medical Council of England regarding the Lincoln-Jefferson University is that it is "of more than dubious nature." Furthermore, the Council considers association with this university as "unprofessional conduct" and has demanded an explanation from the British medical men who in any way have been connected with either the International Medical College or the Lincoln-Jefferson University.

Use of Lincoln-Jefferson Pharmacy Degrees Unlawful in New York

The barter in medical diplomas by American diploma mills has been fairly well safeguarded and made difficult because of the vigilance of the American Medical Association. This probably accounts for the fact that the Lincoln-Jefferson University selected pharmacy as a safer and more remunerative field in which to work. Indeed, of the 536 degrees (at least) issued by the Lincoln-Jefferson University during the two brief years between September, 1920, and 1922, inclusive, 234 were in pharmacy—a rich field![5] Divinity was the next best field, in which eighty-seven degrees were issued!

---

[2] From a report in the Educational Record, January, 1926.

[3] The charter of the Oriental University was revoked, Dec. 25, 1923, and on Jan. 9, 1926, "Bishop Helmuth P. Holler, Ph.D., D.Ps.T., LL.D., h.c., its founder, president and corresponding secretary, was given the maximum sentence of two years in jail and a fine of $1,000 by Mr. Justice Stafford of the Supreme Court of the District of Columbia.

[4] *Indian Medical Gazette, Calcutta.*

Reports show that early in 1924 Dr. Augustus S. Downing, director of professional education in New York, in a letter to the Lincoln-Jefferson University, denied statements made by "Dr." Irving I. Jacobs, dean of this university's school of pharmacy, that its degrees were recognized by the New York Board of Regents. In this letter Dr. Downing states:

> "I am in receipt of a special announcement of the Lincoln-Jefferson University; founded 1897; Rev. Dr. John F. B. Walker, President; School of Pharmacy—Post Graduate Department, from which circular I quote:
>
>> We advise that our graduates add the initials "Ill." after our degrees when displaying them on show windows, labels, etc., to show that the degrees were obtained from a university incorporated and chartered in the state of Illinois. This is in accordance with an arrangement entered into between the Lincoln-Jefferson University and the New York Board of Regents represented by Dr. Downing.
>
> "This advertisement must stop at once since no such arrangement was made between the Lincoln-Jefferson University and myself as representing the Board of Regents. Furthermore, at the last session of the legislature a law was enacted which reads as follows:
>
>> "Correspondence Schools. No person, firm or corporation shall conduct in this state a correspondence school unless such person, firm or corporation shall first have secured the approval of the Board of Regents. Such approval shall be secured and granted in accordance with rules and regulations adopted by such board. Violation of this section shall constitute a misdemeanor.
>
> "I am therefore advising all of those who are listed as having received the degree from your institution that such degree cannot be used in this state."

HISTORY OF "DR." JACOBS, DEAN OF PHARMACY

Reports of the activities of "Dr." Irving I. Jacobs[6] are particularly interesting. Besides being one of the deans of the Lincoln-Jefferson University, he also conducted the "Connecticut School of Pharmacy,". New Haven, which "obtained degrees for its part-time students from the Chicago diploma mill." Jacobs is said to have graduated about 1914 from the New Jersey College of Pharmacy, and afterward opened the "Hudson Institute of Pharmacy" in a hall room in Jersey City, N. J. He was also listed as an instructor at the "Columbia College of Jersey City," which had catalogues printed, but never functioned, its charter having been revoked by the New Jersey State Board of Education. It is said that Jacobs then started a school of pharmacy of his own in Brooklyn. For a time he is said to have conducted a class in Boston and another in New York, devoting one afternoon a week to each. He is said to look after all mail addressed to the department of pharmacy of the Lincoln-Jefferson University, which is forwarded to him at New Haven.

Summary

The information outlined in the foregoing pages contains facts that can be stated positively, as follows:

1. Three medical diplomas, one from Lincoln-Jefferson University and two from the University of Trinity College, were issued to persons in Japan.
2. Lincoln-Jefferson University, the University of Trinity College and the American University (Los Angeles) have no buildings, no laboratories, no grounds, no libraries or other equipment such as are considered as absolutely essential by bona fide reputable universities.
3. No one of these institutions is named in the list of colleges and universities approved by any standardizing agency deemed reliable by the Council on Medical Education and Hospitals.
4. The headquarters of the first two great (?) institutions consists of two small adjoining rooms in an office building in Chicago; the third is housed in one small upper room in Los Angeles, which served both as the "office" and as the living and sleeping quarters of the "dean." The furniture and total equipment of the first two "universities" consisted only of an ordinary desk and a few chairs, while the room of the Los Angeles institution boasted, in addition, a dilapidated bed.
5. Reliable reports show that Rev. John F. B. Walker, Ph.D., D.D., LL.D., F.R.G.S., and the Rev. A. W. Slade, A.K.C., M.A., D.D., LL.D., the two men at the head of this chain of invisible universities are rectors of Episcopal churches in their home cities—just as the head of the Oriental University reverently signed himself "Bishop."
6. The catalogue of Lincoln-Jefferson University contains the statement that M.D. degrees are "not offered by any reputable school of correspondence" and that "we are not prepared to offer courses leading to these degrees"; nevertheless, behold the "degrees in medicine" issued to three Japanese, reproduced in this article!
7. The institution is not loath to mislead the public, as shown by the following statement in its announcement: "All diplomas are issued without mention that any part of the work was taken by correspondence."
8. This "university" is considered as "of more than dubious nature" by the General Medical Council of England.
9. Agents of this group of institutions in Italy and India have openly advertised in the newspapers—not the educational advantages, but the degrees of these universities—just as they would advertise any other merchandise offered for sale.
10. The methods followed by the Lincoln-Jefferson University in the distribution and barter in diplomas are very similar to, if not identical with, those followed by the Oriental University which, Dec. 25, 1924, was closed by legal process and whose president, "Bishop" H. P. Holler, Jan. 9, 1926, was convicted and given the maximum penalty, two years in jail and a fine of $1,000.
11. The relationship of the Lincoln-Jefferson University and its affiliated institutions with the now defunct Oriental University is further suggested by the fact that agents or salesmen of the one have also represented the other and have used the same flagrant methods of advertising in connection with the two institutions.
12. Evidence shows that in the United States the Lincoln-Jefferson University's most prolific field of activity was in the barter of pharmacy degrees carried on in New York, until action by the Board of Regents and publicity by the *Pharmaceutical Era* put a stop to it.
13. Mention is made of numerous institutes, colleges, schools and universities in the literature of the Lincoln-Jefferson University relating to law, theology, medicine, pharmacy, etc., many of which, if existing at all, were created through the lack of adequate safeguards in this country over the chartering of educational institutions. Among the institutions named are several known to be of extremely low grade educationally, and for several others records show evidence of misleading or disreputable practices.
14. According to the Lincoln-Jefferson University's announcements, in slightly more than two years, degrees were issued to 536 different persons, these degrees being of at least thirty-eight varieties, others, evidently, to be had for the asking—and, of course, the fee. The title of "professor" was also granted in several instances. It is interesting to note that degrees were granted not only in "divinity," but also in "theology," in "sacred theology," altogether eighty-seven having been granted under these labels. Degrees also were granted in "law," "laws," "juris," "civil law" and "commercial law."
15. Needless to say, neither these "universities" nor their degrees are given recognition by any of the high grade, well known or established colleges or universities.

---

[5] This "university's" activities in the barter of pharmacy degrees are further shown in the Pharmaceutical Era of Jan. 19, 1924.

[6] Pharmaceutical Era, Jan. 19, 1924.

STATE BOARD STATISTICS FOR 1925

ANNUAL PRESENTATION BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION OF RESULTS OF STATE BOARD EXAMINATIONS

On pages 1534 to 1541 are three tables, A, B and C, giving in detail the results of the various state medical license examinations held during 1925. All state boards sent in reports, and the statistics are complete. The data in these tables are presented in the same manner as heretofore. The majority of graduates take the examination in the state in which the college is located, as shown by the dark diagonal zone of figures passing from the upper left to the lower right corner of each table. The marginal numbers enable one to follow readily the line for any college.

Graduates of All Years Examined in 1925

Table A shows the results for all candidates who took examinations in 1925, regardless of the years in which they graduated. This shows that altogether 5,956 candidates were examined last year, or 606 more than in 1924, and 1,258 more than in 1923. Since 1906 and until 1919, there was the expected decrease in the totals examined, owing chiefly to the general reorganization of medical education and, prior to 1919, in the decreasing numbers of students and graduates. Since 1918 there has been a constant increase, except in 1922, when the decrease was due to the small number, 2,529—the war class—that graduated in that year. Of the 5,404 examined in 1925, 9.3 per cent failed, as compared with 11.9 in 1924.

There were sixty-eight medical colleges in the United States granting degrees in 1925 which had graduates examined. This is eighty-five less than in 1905, when graduates from 153 medical colleges were examined. The statistics covering schools that have ceased to exist are included in the line for "miscellaneous colleges."

Table 1.—*Foreign Physicians Examined*

Year	Canada			Other Foreign Graduates			Totals		
	Examined	Failed	Per cent	Examined	Failed	Per cent	Examined	Failed	Per cent
1917	34	8	23.5	79	37	46.8	113	45	39.8
1918	29	10	31.5	45	17	37.8	74	27	36.5
1919	71	22	31.0	67	30	44.8	138	52	37.7
1920	85	21	24.7	86	33	38.4	171	54	31.6
1921	84	20	23.8	178	77	43.2	262	97	33.2
1922	73	9	12.3	186	76	40.9	259	85	32.4
1923	140	17	12.1	371	165	44.5	511	182	35.6
1924	212	14	6.6	591	231	39.1	803	245	30.5
1925	319	27	8.4	523	205	39.2	842	232	27.6
Totals	1,047	148	14.1	2,126	871	41.4	3,173	1,019	32.1

Applicants Examined from Canada and Abroad

Graduates of Canadian medical schools were examined last year in twenty-nine states. Last year 319 were examined, as compared with 212 in 1924, 140 in 1923, and eighty-two in 1922. The largest number, seventy, were examined in New York, the next largest number being forty-one examined in Michigan. The figures for each college are given so as to show the successes and failures of its graduates at the examinations. Of the 319 candidates examined, twenty-seven, or 8.4 per cent, failed.

The number of foreign physicians seeking licensure in the United States has been steadily increasing since the World War. There were 523 in 1925, exclusive of those from Canada, as compared with 591 in 1924, 371 in 1923 and 186 in 1922. Of the 523 examined in 1925, 205, or 39.2 per cent, failed. This year, foreign graduates were examined in thirty-one states, the largest number, 236, being examined in New York, of whom ninety-seven, or 69.8 per cent, failed. From all foreign countries, including Canada, 842 candidates were examined, of whom 610 passed and 232, or 27.6 per cent, failed. As shown in table 1, the number of applicants from foreign countries has rapidly increased since the conclusion of the World War.

Caution in Forming Conclusions

In making comparisons on the basis of these statistics, the reader must keep in mind (*a*) the number of graduates examined; (*b*) the number of states in which a school's graduates were examined, and (*c*) the character of the board making the examination and the methods employed. Some boards refuse to examine graduates of inferior medical colleges, while others admit not only graduates of low-grade medical colleges but also osteopaths to the physicians' and surgeons' examination. Some boards hold fairly severe examinations, which include practical laboratory and clinical tests, or they mark the papers strictly, while others are more lenient. It is particularly important, in forming conclusions based on these statistics, to note for each college the states ir which its graduates *are not admitted to examinations,* information set forth in table D. Very few state boards nov admit graduates of low-grade medical schools to thei examinations.

Undergraduates and Osteopaths Examined as Physicians During 1925

For the last five years, the few undergraduates examinec have been accidental or are exceptional instances. In 1925 seven undergraduates were examined. One undergraduat each was licensed by examination in Arizona,[1] Arkansas, Colorado[3] and Kentucky, while two failed in Colorado anc one in Illinois. In 1906, by contrast, there were 703 undergraduates examined, of whom 342 were licensed. The doo is now carefully guarded, therefore, against those whose medical training is known to be incomplete. Several boards however, continue to register as physicians and surgeons, b examination or by reciprocity, graduates of osteopathic colleges, which, if measured by the same standards as medica schools, could be graded only low in class C. Of the fifty-five osteopaths that were examined as physicians in fou states in 1925, twenty-three were licensed—thirteen in Massachusetts, five in Texas, three in Colorado, and two in Wisconsin. In two of these states—Colorado and Texas—th boards refuse to recognize graduates of class C medica schools (see table D); nevertheless, this year Colorado examined thirty-one graduates of class C medical schools, o whom seventeen were registered, while Colorado and Texa examined graduates of osteopathic colleges, which are nothing more than low type medical schools.

Recent Graduates Examined During 1925

Table B gives the results for graduates of 1921 to 1925, inclusive, who were examined during 1925. This table deal with recent graduates, and is the fairest basis for comparison between colleges. Of all candidates examined in 1925, 4,958

(CONTINUED ON PAGE 1541)

---

[1] The applicant in Arizona held a diploma from the Pacific Medical College, which official reports designate as a diploma mill.

[2] The nongraduate licensed in Arkansas is reported as a graduate in 1899 of "Grant University," Chattanooga, Tenn. The medical department of this university was the Chattanooga Medical College, a regular and not an eclectic institution. The complete official alumni list of this college does not include the name of this applicant.

[3] In Colorado the board is required to admit to its examinations any applicant whether he is a graduate or not. It is very seldom that one passes the examination.

(CONTINUED FROM PAGE 1533)

or 83.2 per cent, were recent graduates, and of this number 5 per cent failed, as compared with 9.3 per cent for all candidates.

Old Practitioners Examined During 1925

Table C is arranged so as to show in comparison the results for graduates of all years (first column), for recent graduates (second column), for graduates of 1920 and previous years (third column), and for graduates of 1925 (fourth column). Of the graduates of 1920 and previous years—"old practitioners"—936 were examined, and of this number 273, or 29.2 per cent, failed, as compared with 5 per cent of failures for recent graduates. The numbers of these candidates will be diminished (see table 3) as state licensing boards extend their provisions for reciprocity, or the endorsement without further examination of a license granted by another state where a physician's qualifications are otherwise satisfactory. As a rule, states that have limited or no reciprocal relations with other states (Florida and New York—see table F) examine larger numbers of old practitioners.

Graduates of 1925 Examined During 1925

Table C also gives the results for the graduates of 1925 who were examined during the year by the state boards, and shows that 3,138, or 52.7 per cent, of all candidates examined during the year graduated in 1925, including thirty who graduated from Canadian medical colleges. Educational statistics show that the medical colleges of the United States graduated 3,974 students last year; therefore, 79 per cent of all graduates of 1925 took examinations for license during that year. In some of the states, graduates in medicine are allowed to serve as hospital interns without first becoming licensed practitioners, which accounts for some of the remaining 21 per cent. Of the 3,138 graduates of 1925 who were examined, forty-eight, or 1.5 per cent, failed.

Nonrecognition of Medical Colleges

Table D shows for each college, from official reports, the states in which its diplomas are not given full recognition. This table also shows the latest rating given to each college by the Council on Medical Education and Hospitals. For the student who is selecting a medical college, the facts in table D are of extreme importance. There are sixty-six, or 82.5 per cent, of all medical colleges which have complete recognition in all states. There are five others for which the few instances of nonrecognition are due to certain technicalities in state board requirements. If the student gets his medical training in one of the remaining nine colleges, however, he will find on graduation that he cannot secure a license to practice in from seven to forty-eight states.

During the thirteen years that table D has been published, the proportion of fully recognized colleges has increased from 29 per cent in 1913 to 82.5 per cent in 1925.

Of the fifty states—counting in Alaska and the District of Columbia—the state licensing boards of forty-eight, to some extent at least, are now utilizing their legal power to refuse recognition to medical colleges that do not meet their educational requirements. In the other two states, the boards do not have the authority to enforce reasonable standards. In Arkansas and Connecticut, although the regular medical boards are debarring graduates of low-grade colleges, such candidates have been licensed by the separate eclectic boards.

Table 2.—*Recognition of Medical Colleges (Based on Table D)*

Not recognized in 45 to 48 states	..	.	..	6	6
Totals	107	98	88	80	80

It is evident that if the graduates of inferior medical colleges are not eligible for license in the majority of states, they will flock to the few that still grant such recognition. The following states, therefore—Arkansas (eclectic board), Massachusetts and the District of Columbia—will remain the dumping ground for the output of low-grade medical colleges until the licensing boards obtain and exercise the needed authority to bar them. Illinois will be the chief recipient of the graduates of the Chicago Medical School, which is recognized in that state.

Study of Totals and Percentages

A study of totals and percentages (table 3) as compared with previous years is of interest. The number, 5,956, examined in 1925 was 606 more than were examined in 1924, 1,258

(CONTINUED ON PAGE 1543)

TABLE D—RECOGNITION OF MEDICAL COLLEGES

This table, based on official reports, shows in what states diplomas granted by certain medical colleges are not recognized as an [illegible] for the license to practice medicine

Colleges marked (x) have been reported as not recognized by the states in the columns of which the letter appears

---

* Ten medical colleges give only the first two years of the medical course.

† Classification revised to May 15, 1926.

1. Formerly the Chicago Hospital College of Medicine. Has advertised also under the name of "Fort Dearborn Hospital School."

2. This college claims to be an eclectic college, but is reported as not recognized by the National Eclectic Medical Association. It is an offshoot of the Eclectic Medical University, an institution which during its existence was rated in Class C. The new college has refused inspection. This school, and the St. Louis College of Physicians and Surgeons, were involved in the Missouri diploma mill scandal in 1923-1924.

3. Formerly the Central College of Osteopathy; in 1917 became the Central College Medical Department; present title in 1918.

4. These schools have not been inspected by the Pennsylvania Bureau of Medical Education and Licensure.

(x) According to official reports the licensing boards of the states thus indicated do not grant full recognition to, or have taken action refusing to admit to their examinations graduates of the colleges marked by this letter—x.

(CONTINUED FROM PAGE 1541)

more than in 1923, and 1,963 more than in 1922. The fluctuations in the numbers examined indicate similar fluctuations in the numbers of graduates in the various years. Indications are that the totals will be gradually increased during the next five years. By all methods—examination, reciprocity under exemption, etc.—7,194 physicians were *licensed* during 1925, 641 more than in 1924, 873 more than in 1923, but 671 less than in 1906, when 7,865 physicians were licensed. The number of physicians licensed in 1925 is the largest since 1910, but includes physicians (see table 4) having decidedly higher qualifications.

Totals Examined in Five Years

Table E shows the number registered and the number rejected in each state by examination for each of the last five years. A comparison of this table with the statistics in the last educational number of The Journal (Aug. 22, 1925, p. 593, table 11) shows—what would be expected—that the states having the largest numbers of medical graduates examined the largest numbers of physicians. New York leads, having examined 4,475 candidates in five years, followed by Illinois, with 1,998. Altogether, 24,804 physicians were *examined* by state boards in five years, an average of 4,961 each year, and, of these, 4,365, or 88 per cent, were licensed each year.

Table 3.—*Results for This and Previous Years*

Year	All Candidates Examined				Recent Graduates		Older Graduates		Nondescript		Registered without Written Examination	Total Registered
	Examined	Passed	Failed	Percentage Failed	Examined	Percentage Failed	Examined	Percentage Failed	Examined	Percentage Failed

Total Registration in 1925

The tables thus far described have referred only to those registered by examination. Table F, however, shows the total number who received licenses in each state, including those registered by examination, by reciprocity and under various exemption clauses. Altogether, 7,194 physicians were registered by all methods during 1925, the largest number since 1910. The total registered in 1918—4,185—was the lowest number registered in any year since the publication of these statistics was begun, owing undoubtedly to the war. In 1906 the total number registered was 7,865, which was the largest number registered in any year.

More than 100 were registered by all methods in twenty-three states; more than 200 in nine, and more than 300 in seven, the largest numbers being 1,078 in New York, 584 in California, 438 in Florida and 383 in Ohio.

Of those licensed in California, 291, or 49.8 per cent, were registered by the endorsement of licenses granted by other states. Several boards examined and licensed osteopaths as "physicians and surgeons." Massachusetts licensed thirteen, Texas five, Colorado three and Wisconsin two. Altogether, twenty-three osteopaths—graduates of colleges decidedly inferior to the lowest grade medical schools—were licensed as physicians and surgeons.

TABLE D—RECOGNITION OF MEDICAL COLLEGES

This table, based on official reports, shows in what states diplomas granted by certain medical colleges are not recognized as an acceptable qualification for the license to practice medicine

Colleges marked (x) have been reported as not recognized by the states in the columns of which the letter appears

---

* Ten medical colleges give only the first two years of the medical course.

† Classification revised to May 15, 1926.

1. Formerly the Chicago Hospital College of Medicine. Has advertised also under the name of "Fort Dearborn Hospital School."

2. This college claims to be an eclectic college, but is reported as not recognized by the *National Eclectic Medical Association*. It is an *offshoot of* the *Eclectic Medical University*, an *institution* which during its existence was rated in *Class C*. The new college has refused inspection. This school, and the St. Louis College of Physicians and Surgeons, were involved in the Missouri diploma mill scandal in 1923-1924.

3. Formerly the Central College of Osteopathy; in 1917 became the Central College Medical Department; *present title* in 1918.

4. These schools have not been *inspected* by the Pennsylvania Bureau of Medical Education and Licensure.

(x) *According to official reports the licensing boards of the states thus indicated do not grant* full recognition to, or have taken action refusing to admit to their examinations graduates of the colleges marked by *this* letter—x.

(CONTINUED FROM PAGE 1541)

more than in 1923, and 1,963 more than in 1922. The fluctuations in the numbers examined indicate similar fluctuations in the numbers of graduates in the various years. Indications are that the totals will be gradually increased during the next five years. By all methods—examination, reciprocity under exemption, etc.—7,194 physicians were *licensed* during 1925, 641 more than in 1924, 873 more than in 1923, but 671 less than in 1906, when 7,865 physicians were licensed. The number of physicians licensed in 1925 is the largest since 1910, but includes physicians (see table 4) having decidedly higher qualifications.

Totals Examined in Five Years

Table E shows the number registered and the number rejected in each state by examination for each of the last five years. A comparison of this table with the statistics in the last educational number of The Journal (Aug. 22, 1925, p. 593, table 11) shows—what would be expected—that the states having the largest numbers of medical graduates examined the largest numbers of physicians. New York leads, having examined 4,475 candidates in five years, followed by Illinois, with 1,998. Altogether, 24,804 physicians were *examined* by state boards in five years, an average of 4,961 each year, and, of these, 4,365, or 88 per cent, were licensed each year.

Table 3.—*Results for This and Previous Years*

Year	All Candidates Examined				Recent Graduates		Older Graduates		Nondescript		Registered without Written Examination	Total Registered
	Examined	Passed	Failed	Percentage Failed	Examined	Percentage Failed	Examined	Percentage Failed	Examined	Percentage Failed

Total Registration in 1925

The tables thus far described have referred only to those registered by examination. Table F, however, shows the total number who received licenses in each state, including those registered by examination, by reciprocity and under various exemption clauses. Altogether, 7,194 physicians were registered by all methods during 1925, the largest number since 1910. The total registered in 1918—4,185—was the lowest number registered in any year since the publication of these statistics was begun, owing undoubtedly to the war. In 1906 the total number registered was 7,865, which was the largest number registered in any year.

More than 100 were registered by all methods in twenty-three states; more than 200 in nine, and more than 300 in seven, the largest numbers being 1,078 in New York, 584 in California, 438 in Florida and 383 in Ohio.

Of those licensed in California, 291, or 49.8 per cent, were registered by the endorsement of licenses granted by other states. Several boards examined and licensed osteopaths as "physicians and surgeons." Massachusetts licensed thirteen, Texas five, Colorado three and Wisconsin two. Altogether, twenty-three osteopaths—*graduates of colleges decidedly* inferior to the lowest grade medical schools—were licensed as physicians and surgeons.

Total Registration in Five Years

Table G permits the reader to note the registrations in each state for the last five years. In the totals registered there was a decrease during the first two years, but an increase during the last three.

In 1925, the total registered was 7,194, an increase of 641. Regardless of the general increases in the numbers registered in 1925, marked decreases are noted in Massachusetts, 113, in New Jersey, 50, and in Missouri, 26. The largest increases in registration were in Florida, 281; New York, 197; Texas, 141; Iowa, 38; Oregon, 36; Nebraska, 35, and Maryland, 28. During the last five years, New York registered 4,340, the highest number, followed by California with 3,125; Illinois with 1,951; Ohio with 1,665; Pennsylvania with 1,613, and Michigan with 1,386. The three lowest registrations are Delaware with 71, Wyoming with 79, and New Hampshire with 82.

This table gives the number of physicians who passed and failed in the examinations in each state during the last five years. The last four columns give the total and the percentage rejected by each state in the five year period. Seven states registered over 1,000 candidates by examination in the five years—New York, Illinois, Pennsylvania, Massachusetts, California, Ohio and Michigan. Altogether 21,827 physicians were registered by examination in the five years, an average of 4,365 each year.

The five states having the highest percentages of failures in the five years were Arizona 31.8, Colorado 30.9, Massachusetts 24.1, Florida 21.7, and California 21.7. Colorado and Massachusetts admitted osteopaths to their examinations as physicians and surgeons and would be expected to have high percentages. On the other hand, in most states the boards refuse to recognize low-grade colleges (see table D) and thereby eliminate inferior candidates prior to the examination, and correspondingly the percentages of failures at examinations are lower. For example, Tennessee rejected only 0.2 per cent of those who took its examinations, but refused to admit graduates of six inferior medical colleges to its examinations. In Idaho, New Mexico and Vermont there were no failures. The next lowest failure percentages were in Indiana, 0.3; Iowa, 0.3, and Minnesota, 0.7.

Totals	4,712	663	29	1,784	6	7,194

This table shows the numbers registered in each state during 1925 by examination, by reciprocity, and by endorsement [illegible] The first three columns show those regis[illegible]luding recent graduates, older practitioners [illegible]duates of nondescript colleges, including any [illegible] licensed as physicians and surgeons. The fourth column shows the number registered by the endorsement of licenses issued by other states (reciprocity) and by certificates of the Army, Navy, Public Health Service and the National Board of Medical Examiners. The fifth column shows those licensed under various exemption clauses in the practice acts—because of high professional standing or by the endorsement of diplomas of recognized medical schools. Massachusetts licensed 13 osteopaths as physicians and surgeons; Texas, 5; Colorado, 3 and Wisconsin, 2. The last column shows for each state the total number of physicians registered by all methods during 1925. Seven states registered over 300 each, these being New York, 1,078; California, 584; Florida, 438; Ohio, 383; Pennsylvania, 367; Illinois, 358 and Michigan, 335. The total registration by all methods was 7,194, an increase of 641 over 1924.

Medical Training of Applicants Licensed in 1925

Table H is of especial interest, since it shows for each state the numbers of candidates coming from medical schools rated in classes A, B and C, thereby indicating the character of the medical training of the candidates licensed during 1925. Of the 7,194 candidates registered, 5,404 were licensed by

Totals	6,348	5,497	6,321	6,553	7,194	31,913

This table shows the totals registered in each state during the last five years. Marked decreases are noteworthy in Illinois, 74; New Jersey, 50; Missouri, 26 and Wisconsin, 24. Marked increases over 1924, however, are noted in Florida, 281; New York, 197 and Texas, 144. During the three years following 1920 the totals registered decreased from 6,557 to 6,321. In the three years since 1923 the totals have again increased to 7,194—the largest number registered in any year since 1910.

In 1925, 23 candidates were licensed by the Arkansas Eclectic Board, including 20 graduates of a class C school and one nongraduate who is rated as of class C.

Of the 31 graduates of class C colleges licensed in Massachusetts, 13 were graduates of osteopathic colleges, which are rated as of class C. In Colorado, of the 18 class C applicants registered, 4 were graduates of osteopathic colleges, and one was a nongraduate.

In Connecticut, in 1925, no candidates were reported as licensed by the Eclectic Board and only one class C candidate (a nongraduate) was licensed in the state by reciprocity.

Illinois harbors the Chicago Medical School, a class C medical college, not now recognized in 47 other states. Massachusetts has two class C colleges, the College of Physicians and Surgeons and the Middlesex College of Medicine and Surgery, but does not have the authority to refuse recognition to low grade institutions. This accounts for the large number of class C graduates licensed in that state. Missouri has three class C colleges, the Kansas City College of Medicine and Surgery, the Kansas City University of Physicians and Surgeons and the St. Louis College of Physicians and Surgeons. The Missouri board refused recognition to these colleges until forced to do so by an amendment to the medical practice law in 1921—an amendment that was repealed in 1923. Missouri registered only one class C graduate in 1925, as compared with 38 in 1923.

Texas reports that class C medical schools are not recognized, but accepted 20 osteopaths who come from schools of equally low or lower type.

Eleven states accepted class C graduates through reciprocity, while they licensed none by examination. Indiana, Iowa and Washington so registered 3 each. One or two each were licensed by reciprocity in eight other states. Altogether, there were 18 class C graduates licensed by reciprocity in states which registered none by examination. On the whole, in 1925, 114 class C graduates were licensed by examination an 57 through reciprocity, a total of 171, 42 more than in 1924.

examination and 1,790 by reciprocity or on presentation of acceptable credentials Those who graduated prior to 1907, when the first classification of medical colleges was completed by the Council on Medical Education, are included among graduates of "Miscellaneous Colleges." Among the graduates of class C schools are included twenty-three osteopaths who were licensed as physicians in Colorado, Massachusetts, Texas and Wisconsin

As will be noted, the largest number of class C graduates was licensed in Massachusetts with 31, followed by Illinois and Texas with 23 each, Arkansas with 21, Colorado with 18, California with 12, and Florida, Indiana, Iowa and Washington with 3 each

New York registered 74 class B graduates—the largest number—followed by Ohio with 36, Florida, 35; California, 33; Illinois, 32, and Pennsylvania, 20 In 1925, only class A graduates were registered by either examination or reciprocity in New Hampshire, Rhode Island, Vermont and Wyoming

Of the 7,194 physicians registered by all methods in 1925, 5,852, or 81 3 per cent, graduated from class A medical colleges, 382, or 5 3 per cent, from class B colleges, 171, or 2.4 per cent, from class C colleges, and 789, or 11.1 per cent, graduated prior to 1907, when the first classification of medical colleges was prepared, or came from foreign medical colleges By comparing these figures with the results for the previous seven years as shown in table 4, it is noteworthy that the *percentages* from class B and class C colleges are steadily decreasing, and the percentage of graduates of class A colleges increasing

Of the 125 graduates of low grade colleges licensed in Arkansas during the last six years, 123 were licensed by the Eclectic Board of Medical Examiners and 2 by the Regular Board

During the six years, 208 graduates of inferior colleges were licensed in California, including 98 osteopaths who were licensed as physicians None have been examined since 1922, however, when a separate osteopathic board was created

Of the 128 class C graduates licensed in Colorado, 73 were osteopaths who are given the same privileges as physicians

During the three years 1921 to 1923, inclusive, the Connecticut Eclectic Board certified for licensure 167 graduates of class C colleges, including graduates of regular, homeopathic and nondescript colleges as well as eclectic None were licensed, however, in the last two years, although in 1925, one candidate was passed by the Eclectic Board but was refused a license by the commissioner of health

Illinois, Massachusetts and Missouri are the homes of class C medical colleges, which accounts for the larger numbers of class C graduates licensed in those states

Note that, in Missouri, 38 class C graduates were licensed in 1923, as a result of the change in the practice law removing the word "reputable" as referring to medical colleges The amendment, however, was repealed in 1923, so that only one class C candidate, an old practitioner, was registered in 1925

Of the 113 graduates of low grade institutions licensed in Texas during the six years, only 16 were by examination, while 97 were by reciprocity. Of those licensed, 67 were osteopaths who are given the same privileges as physicians

This table shows the number of physicians registered in each state through endorsement of other state licenses during 1925. Read from left to right, it shows the total number of physicians registered in the state named and the number of such candidates coming from each of the states named at the top of the various columns. Read from above downward, the figures show the number of physicians who left the state named at the head of the column and went to each of the states named at the left in the corresponding lines, and at the bottom is given the total number of candidates leaving the state to go elsewhere. This bottom line shows also the states in which physicians who registered through reciprocity obtained their original licenses. The total number licensed by reciprocity was 1,784, or 3 less than in 1924.

Training of Physicians Registered in Six Years

Table I is of especial interest and shows the character of the training of physicians registered during the last six years. It is noteworthy that of the 38,332 physicians registered in six years, 28,841, or 75.2 per cent, were graduates of class A medical schools; 2,826, or 7.4 per cent, were graduates of class B schools, and 1,582, or 4.1 per cent, were graduates of class C schools. Graduates of foreign medical schools and those who graduated prior to 1907 from medical schools which, since that year, have not always been rated in class A, have been grouped under "Miscellaneous Graduates"; and, during the six years, 5,083 of these graduates were registered.

The largest number of candidates registered who graduated from class C colleges was 248 in Massachusetts, the next highest being 208 in California, 169 in Connecticut,[3] 154 in Illinois, 128 in Colorado, 123 in Arkansas, and 113 in Texas.

Note the number of class C graduates licensed in each of several states during the six years. In Arkansas, the number licensed ranges from eighteen to thirty-six each year. The number drops abruptly to one in 1924 (an undergraduate). This slump was undoubtedly due to the forced inactivity of the Kansas City College of Medicine and Surgery. In spite of its exposure as a diploma mill in 1923, this institution continues to issue degrees. Although Arkansas licensed twenty-one class C graduates in 1925, including seventeen from the Kansas City College of Medicine and Surgery, only four of these obtained their degrees in 1925.

In Connecticut, only a few such candidates were licensed each year until in 1921, 1922 and 1923 the numbers bounded up to 66, 74 and 27, respectively. The eclectic board had ceased to limit its acceptance of graduates of eclectic colleges, but had accepted all who applied, including graduates of homeopathic and regular schools. Note, however, that in 1924 and 1925 no class C graduates were licensed—a result of the diploma mill inquiry. In Illinois the numbers are larger or smaller as the board in that state fluctuates in its recognition of the Chicago Medical School, a typical class C institution. In Massachusetts there are two class C colleges—the board not having the authority to decide whether or not a medical school is "reputable." In Missouri, which harbors three of the class C schools, the board persistently refused recognition to those schools until late in 1922 the practice law was amended, forcing the board to examine class C graduates—hence the larger number in 1923. In

---

[3] In Connecticut, legal proceedings are being conducted to revoke *many of these licenses.*

1925, after the board's power was restored and the low-grade medical schools were again refused recognition, only one such candidate was registered.

Registration by Reciprocity

Table J shows the numbers of physicians registered in 1925 without examination on presentation of satisfactory credentials, which included a license issued by some other state board or by the National Board of Medical Examiners. Some state boards—Arizona, California, Colorado, Delaware, Maryland, New Hampshire, New Jersey and North Carolina, as examples—accept a physician's credentials if satisfactory, whether or not the state board issuing the original license returns the favor. Altogether, 1,784 physicians were licensed in 1925 on the basis of "reciprocity"—without being compelled to undergo a second trying examination.

Table K.—*Reciprocal Registration in Five Years (Showing What States Issued Original Licenses)*

Foreign and Misc.	7	10	11	5	11	44
Totals	2109	1914	2144	1787	1784	9768

This table shows that 9,768 physicians were registered through reciprocity during the last five years, an average of 1,954 each year. After 1920 there was a reduction each year, including 1922. In 1923 there was an increase of 314, but in 1925 a reduction of 674. Of the 9,768 candidates registered during the five years, 1,255 obtained their original licenses in Illinois, the next largest number being 570 in New York.

Table K shows what state boards granted the original licenses of those registered elsewhere under the reciprocity provision during the last five years. Of the 9,768 physicians licensed through reciprocity during the last five years, the largest number coming from any one state was 1,255 who obtained their original licenses in Illinois. Although New York has a larger number of medical college graduates each year than Illinois, only 570 physicians obtained original licenses in New York and registered elsewhere through reciprocity in the last five years. This is accounted for by the fact that Illinois has reciprocal relations with twenty-eight states, while New York has relations with only eight.

Unlicensed Graduates

Table L shows the number of physicians in each graduating class since 1910 who, evidently, have not yet received licenses from some state licensing board. Besides the total number of graduates each year, the table shows for 1925 the numbers remaining unlicensed in each class since 1910. The number of graduates of 1925 who are unlicensed are mostly interns, while those in previous classes include teachers, laboratory workers, including bacteriologists and pathologists, and others indirectly connected with the medical profession, but not engaged in diagnostic work. Some of these unlicensed physicians reside abroad and may have received the right to practice, but have never secured licenses in the United States. The fact that many internships extend over eighteen months or two years doubtless accounts for the large number of graduates of 1924 who are still unlicensed. The number of unlicensed graduates of Canadian schools is also shown.

Of the 2,777 graduates in the United States who are still unlicensed (fourth and fifth column), 260 have each failed in from one to twelve separate examinations for licensure, making a total of 574 failures. It is an interesting fact, although not shown in the table, that approximately half of the individuals who failed are graduates of class C medical schools.

Improved Standards of Licensure

Table M shows the states that have adopted one or two years of college work as a minimum standard of preliminary education for those who seek the license to practice medicine, and also the states that require a year's internship in a hospital. The first, third and fifth columns show, respectively, when the requirements affected students matriculating in medical colleges, and the second, fourth and sixth columns give the years in and after which all applicants for licenses are affected by the requirement. This table shows the rapidity with which higher requirements of preliminary education were adopted by state boards since 1908. Prior to that year, no state was requiring as a standard of preliminary education more than a high school education. There are now

Table L.—*Number of Medical Graduates in Each of the Years Given Who Have Not Yet Obtained Licenses to Practice*

* No information regarding failures of graduates before Canadian Boards.

forty-three states that have adopted the higher standard and, of these, thirty-nine require two years of college work. It is understood that in every instance the college work must have included courses in physics, chemistry and biology. Although the term "two years of college work" is mentioned, it is the content of those years that is asked for. That specification is used in the absence of a more fitting term describing the desired qualifications. As shown in table M (and the footnotes), in the District of Columbia, Massachusetts and Wyoming no standards of preliminary education have been legally authorized or adopted.

There are twelve states in which an internship in a general hospital is required as an essential qualification for the license to practice medicine. There are now more than enough hospitals seeking interns to provide places for all graduates each year, so that other state boards would be justified in requiring all applicants to possess this additional qualification.

TABLE M.—*State Requirements of Preliminary Education*

There are now forty-two states (counting Alaska Ter.) which have adopted requirements of preliminary education in addition to a standard four-year high school education. Of this number thirty-nine now require the two year standard. Twelve states have adopted also the requirement of a hospital internship as an essential for the license. These states, and the time the higher requirements became or become effective are as follows:

State Examining Board of	One Year of College Work		Two Years of College Work		A Hospital Internship

* Require a four-year high school education or its equivalent.
† *No fixed standard.*
1. The higher standards in Arkansas and Connecticut are evidently not enforced by the sectarian licensing boards of those states.

IMPROVEMENTS IN LICENSURE SINCE 1904

In table N, the advances in standards of licensure are shown for all states since 1904. The most marked increase is in regard to the requirement of college work in forty-three states—referred to also in table M. An equally great increase is shown in the number of states—now forty-seven—which are refusing to recognize low-grade medical colleges. One other state, Arkansas, could be added to the two lists referred to, were it not for the eclectic board, which is still "recognizing" the inferior schools.

Although marked improvements have been made in state requirements for licensure, nevertheless there is still room for improvement, as indicated by the last column. The greatest needs are for a wider requirement of (*a*) the hospital intern year; (*b*) two years of premedical college work, and (*c*)—a matter of more vital importance—practical tests in the licensing examinations. The states in which the boards are making a really effective use of practical examinations are Illinois, Massachusetts, Minnesota, North Dakota, Ohio and South Dakota. That method is being followed to a certain extent in a few other states.

TABLE N.—*Advances in State License Requirements in Twenty Years*

Requirement or Provision	States Having Provision for			States Still Having No Provision for
	1904	1925	Increase	
Preliminary Education—				
Any requirement	20	46	26	4[1]
A standard four-year high school education or higher	10	46	36	4[1]
One year or more of college work	0	43	43	7[2]
Two years of college work as a minimum	0	39	39	11[2]
That all applicants be graduates of a medical college	36	49	13	1[3]
That all applicants undergo an examination for license	45	50	5	0
Hospital intern year required	0	12[2]	12	38
Full authority by board to refuse recognition to low-grade colleges	14	48	34	2[4]
Boards refusing to recognize low-grade colleges	5	46[5]	41	4[1]
Reciprocal relations with other states	27	45	18	5[6]
Single boards of medical examiners	36	45	9	5[7]

1. District of Columbia, Massachusetts, Wyoming and (because of its eclectic board) Arkansas.
2. See Table M and footnotes.
3. Colorado.
4. District of Columbia and Massachusetts.
5. See Table D. In two states, Arkansas and Connecticut, each of which has three separate boards, only the regular (non-sectarian) boards have refused recognition to low standard medical colleges and have enforced higher standards of preliminary education.
6. Alaska, Connecticut, Florida, Massachusetts, Rhode Island. To this list should be added the outlying territories of Canal Zone and the Philippine Islands, which have no provision for reciprocity. Porto Rico has recently established reciprocal relations with New York.
7. Multiple boards still remain in Arkansas, Connecticut, District of Columbia, Louisiana and Maryland.

IN CONCLUSION

In the publication of these statistics, the endeavor has been to show the actual facts, a knowledge of which is always beneficial. We reiterate our acknowledgments to the officers of state licensing boards for their ready cooperation and the complete reports they have furnished. We believe that the information here published will be of service to the medical colleges and the state boards as well as to the public.

NATIONAL BOARD OF MEDICAL EXAMINERS

The National Board of Medical Examiners was organized in 1915. It now consists of twenty-one members, including the three Surgeon Generals of the Army, Navy and Public Health Service, and one other representative of each of those services, three representatives of the state medical licensing boards and twelve members appointed at large. The personnel of the board at present is as follows:

Dr. Horace D. Arnold, president; Major-Gen. Merritte W. Ireland, Surgeon General, United States Army; Rear Admiral Edward R. Stitt, Surgeon General, United States Navy; Surg. Gen. Hugh S. Cumming, United States Public Health Service; Com. Charles M. Oman, Col. Joseph F. Siler, Surg. George W. McCoy, Dr. Walter E. Garrey, Dr. Walter L. Bierring, Dr. Allen B. Kanavel, Dr. David Strickler, Mr.

1925, after the board's power was restored and the low-grade medical schools were again refused recognition, only one such candidate was registered.

REGISTRATION BY RECIPROCITY

Table J shows the numbers of physicians registered in 1925 without examination on presentation of satisfactory credentials, which included a license issued by some other state board or by the National Board of Medical Examiners. Some state boards—Arizona, California, Colorado, Delaware, Maryland, New Hampshire, New Jersey and North Carolina, as examples—accept a physician's credentials if satisfactory, whether or not the state board issuing the original license returns the favor. Altogether, 1,784 physicians were licensed in 1925 on the basis of "reciprocity"—without being compelled to undergo a second trying examination.

TABLE K.—*Reciprocal Registration in Five Years (Showing What States Issued Original Licenses)*

State	Physicians Going from States Named During					Total
	1921	1922	1923	1924	1925

Foreign and Misc.	7	10	11	5	11	44
Totals	2109	1914	2144	1787	1784	9768

This table shows that 9,768 physicians were registered through reciprocity during the last five years, an average of 1,954 each year. After 1920 there was a reduction each year, including 1922. In 1923 there was an increase of 314, but in 1925 a reduction of 674. Of the 9,768 candidates registered during the five years, 1,255 obtained their original licenses in Illinois, the next largest number being 570 in New York.

Table K shows what state boards granted the original licenses of those registered elsewhere under the reciprocity provision during the last five years. Of the 9,768 physicians licensed through reciprocity during the last five years, the largest number coming from any one state was 1,255 who obtained their original licenses in Illinois. Although New York has a larger number of medical college graduates each year than Illinois, only 570 physicians obtained original licenses in New York and registered elsewhere through reciprocity in the last five years. This is accounted for by the fact that Illinois has reciprocal relations with twenty-eight states, while New York has relations with only eight.

UNLICENSED GRADUATES

Table L shows the number of physicians in each graduating class since 1910 who, evidently, have not yet received licenses from some state licensing board. Besides the total number of graduates each year, the table shows for 1925 the numbers remaining unlicensed in each class since 1910. The number of graduates of 1925 who are unlicensed are mostly interns, while those in previous classes include teachers, laboratory workers, including bacteriologists and pathologists, and others indirectly connected with the medical profession, but not engaged in diagnostic work. Some of these unlicensed physicians reside abroad and may have received the right to practice, but have never secured licenses in the United States. The fact that many internships extend over eighteen months or two years doubtless accounts for the large number of graduates of 1924 who are still unlicensed. The number of unlicensed graduates of Canadian schools is also shown.

Of the 2,777 graduates in the United States who are still unlicensed (fourth and fifth column), 260 have each failed in from one to twelve separate examinations for licensure, making a total of 574 failures. It is an interesting fact, although not shown in the table, that approximately half of the individuals who failed are graduates of class C medical schools.

IMPROVED STANDARDS OF LICENSURE

Table M shows the states that have adopted one or two years of college work as a minimum standard of preliminary education for those who seek the license to practice medicine, and also the states that require a year's internship in a hospital. The first, third and fifth columns show, respectively, when the requirements affected students matriculating in medical colleges, and the second, fourth and sixth columns give the years in and after which all applicants for licenses are affected by the requirement. This table shows the rapidity with which higher requirements of preliminary education were adopted by state boards since 1908. Prior to that year, no state was requiring as a standard of preliminary education more than a high school education. There are now

TABLE L.—*Number of Medical Graduates in Each of the Years Given Who Have Not Yet Obtained Licenses to Practice*

Class of	United States Medical Schools				Canadian Medical Schools

Single boards of medical examiners	36	45	9	6[7]

1. District of Columbia, Massachusetts, Wyoming and (because of its eclectic board) Arkansas.
2. See Table M and footnotes.
3. Colorado.
4. District of Columbia and Massachusetts.
5. See Table D. In two states, Arkansas and Connecticut, each of which has three separate boards, only the regular (non-sectarian) boards have refused recognition to low standard medical colleges and have enforced higher standards of preliminary education.
6. Alaska, Connecticut, Florida, Massachusetts, Rhode Island. To this list should be added the outlying territories of Canal Zone and the Philippine Islands, which have no provision for reciprocity. Porto Rico has recently established reciprocal relations with New York.
7. Multiple boards still remain in Arkansas, Connecticut, District of Columbia, Louisiana and Maryland.

IN CONCLUSION

In the publication of these statistics, the endeavor has been to show the actual facts, a knowledge of which is always beneficial. We reiterate our acknowledgments to the officers of state licensing boards for their ready cooperation and the complete reports they have furnished. We believe that the information here published will be of service to the medical colleges and the state boards as well as to the public.

NATIONAL BOARD OF MEDICAL EXAMINERS

The National Board of Medical Examiners was organized in 1915. It now consists of twenty-one members, including the three Surgeon Generals of the Army, Navy and Public Health Service, and one other representative of each of those services, three representatives of the state medical licensing boards and twelve members appointed at large. The personnel of the board at present is as follows:

Dr. Horace D. Arnold, president; Major-Gen. Merritte W. Ireland, Surgeon General, United States Army; Rear Admiral Edward R. Stitt, Surgeon General, United States Navy; Surg. Gen. Hugh S. Cumming, United States Public Health Service; Com. Charles M. Oman, Col. Joseph F. Siler, Surg. George W. McCoy, Dr. Walter E. Garrey, Dr. Walter L. Bierring, Dr. Allen B. Kanavel, Dr. David Strickler, Mr.

John G. Bowman, Dr. Eugene L. Opie, Dr. Lewis A. Conner, Dr. J. M. T. Finney, Dr. W. S. Leathers, Dr. O. H. Perry Pepper, Dr. J. Whitridge Williams and Dr. Howard T. Karsner. The secretary-treasurer is Dr. J. S. Rodman, and the managing director is Mr. E. S. Elwood.

Up to Dec. 31, 1921, eleven examinations had been held, as follows.

Date of Examination	Where Held	Total Examined	Passed	Failed	Percentage Failed
Oct., 1916	Washington	10	5	5	50.0
June, 1917	Washington . .	12	9	3	33.3
Oct., 1917	Chicago . . .	28	22	6	21.5
Jan., 1918	New York ...	20	18	2	10.0
Apr., 1918	Ft. Riley, Ft. Oglethorpe	23	18	5	26.1
Dec., 1918	Chicago, New York	16	15	1	6.3
June, 1919	Philadelphia ..	52	51	1	1.9
Feb., 1920	Chicago, St. Louis .	48	36	12	25.0
May, 1920	Philadelphia	60	46	14	23.3
Feb., 1921	Rochester, Minn .	16	11	5	31.3
June, 1921	Boston	40	37	3	7.5
	Totals	325	268	57	14.4

Following the completion of each examination shown in the table, those who passed were granted the board's certificate, a total by Dec. 31, 1921, of 268.

New Methods Adopted

In 1922, however, the examinations were divided in three parts, as follows: Part I, a written examination in the six fundamental medical sciences: anatomy, including histology and embryology, physiology, physiologic chemistry; general pathology, bacteriology; materia medica and pharmacology. Part II, a written examination in: medicine, including pediatrics, neuropsychiatry and therapeutics; surgery, including applied anatomy, surgical pathology and surgical specialties; obstetrics and gynecology; public health, including hygiene, and medical jurisprudence. Part III, a practical examination in each of the following four subjects: (*a*) clinical medicine, including medical pathology, applied physiology, clinical chemistry, clinical microscopy and dermatology; (*b*) clinical surgery, including applied anatomy, surgical pathology, operative surgery and the surgical specialties of the diseases of the eye, ear, nose and throat; (*c*) obstetrics and gynecology, (*d*) public health, including sanitary bacteriology and the communicable diseases.

Parts I and II are written examinations held in any class A medical school, and part III is an entirely practical and clinical examination given by subsidiary boards in Boston, New York, Philadelphia, Minneapolis, Iowa City, San Francisco, Denver, New Orleans, Baltimore, Galveston, Cleveland, St. Louis, Chicago, Washington, Portland (Ore.), and Nashville. The fees are as follows: registration fee, $5; part I, $10; part II, $15; part III, $50.

Examinations in Part I

Three examinations in part I were held in 1925, as follows:

Date of Examination	Total Examined	Passed	Incomplete	Failed	Percentage Failed
February, 1925 . .	143	116	6	21	14.7
June, 1925	324	205	31	88	27.2
September, 1925	141	79	13	49	34.8
Totals, 1925	608	400	50	158	26.0
1924	591	415	69	107	18.1
1923	507	349	77	81	16.2
1922	388	263	58	67	17.3
Totals	2,094	1,427	254	413	19.7

Altogether, 608 candidates were examined in 1925, as compared with 591 in 1924, 507 in 1923 and 388 in 1922. During the last four years, under the new plan, 2,094 candidates were examined, or more than six times as many as were examined in the six years of the old plan—from 1916 to 1921. Of all those examined in part I during the last four years, 413, or 19.7 per cent, failed.

Examinations in Part II

Three examinations in part II were held in 1925, as follows:

Date of Examination	Total Examined	Passed	Incomplete	Failed	Percentage Failed
February, 1925..............	84	74	...	10	11.9
June, 1925	167	151	...	16	9.6
September, 1925..............	91	84	. .	7	7.7
Totals, 1925	342	300	...	33	9.6
1924	267	227	...	40	14.9
1923	192	170	2	20	10.4
1922 .	109	90	...	19	17.4
Totals	910	796	2	112	12.3

During 1925, 342 candidates were examined in part II, as compared with 267 in 1924, 192 in 1923 and 109 in 1922. Altogether, 910 candidates were examined during the four years, of whom 112, or 12.3 per cent, failed.

Examinations in Part III

The examinations in part III in 1925, which were entirely clinical and practical, were held in several of sixteen subsidiary centers in different parts of the country. The results of the examinations were as follows:

Examinations of	Total Examined	Passed	Failed	Percentage Failed
1922	28	28	..	0.0
1923	76	75	1	1.3
1924 . . .	120	114	6	5.0
1925 .	217	206	11	4.1
Totals . ..	441	423	18	4.1

In 1925, 217 candidates were examined in part III, as compared with 120 in 1924, seventy-six in 1923 and twenty-eight in 1922. During the four years, therefore, 441 candidates were given the final practical examination and, of these, eighteen, or 4.1 per cent, failed.

Total Individuals Examined During Three Years

Year	Parts I, II and III, Excluding Duplications				
	Examined	Passed	Incomplete	Failed	Percentage Failed
1922 .. .	525	381	58	86	16.4
1923	775	594	79	102	13.4
1924 ..	978	756	69	153	15.6
1925 ..	1,167	915	50	202	17.3
Totals.. . ..	3,445	2,646	256	543	15.8

Omitting duplicates, there were 1,167 individuals who took the National Board's examinations during 1925, as compared with 978 in 1924, 775 in 1923, and 525 in 1922. The percentage of failures was 17.3.

In General

Of the failures, it is noted that during the last four years, 19.7 per cent of the candidates failed in part I, 12.3 per cent of the candidates failed in part II, and 4.1 per cent of the candidates failed in part III. Altogether, 3,445 candidates participated in the National Board's examinations during the four years since Jan. 1, 1922, and of these, 543, or 15.8 per cent, failed.

Of those who took examinations in parts I and II during the four years, 256 are listed as incomplete. These are candidates who took examinations in all but one of the subjects included in parts I and II and are listed as incomplete until they have taken an examination also in the remaining subject. In the statistics, however, although mentioned separately, they are counted as successes and not failures.

Recognition of the National Board's Certificates

Holders of certificates from the National Board of Medical Examiners are registered without further examination in thirty-two states, the Canal Zone, Porto Rico and Hawaii.

Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY, MAY 15, 1926

STATE LICENSE STATISTICS

For the twenty-third consecutive year, statistics are offered based on examinations held by state licensing boards during the last calendar year. The publication of these complete statistics is made possible through the cordial support received from the secretaries of licensing boards, to whom we express sincere appreciation.

DATA ACCURATE

Reports of individual examinations have been carefully checked with lists of graduates furnished by medical college officials. In this way any error in regard to the full name of the physician, name of the medical school or year of graduation has been corrected and the accuracy of the statistics thereby assured. Through this checking, also, attention is directed at once to applicants who graduated from diploma mills or other institutions unworthy of consideration as medical schools. In such instances state officials are promptly notified, and in most instances the licenses are revoked.

IMPORTANCE OF LICENSURE STATISTICS

The publication of state licensure statistics permits comparative study of the methods followed by the various boards and their relative efficiency. The statistics also show that, from the standpoint of scientific medicine, methods of licensure have been immensely improved during the last twenty-five years. The attention called to the high percentage of failures of graduates of certain medical schools has led to prompt improvements, or recognition of them is withdrawn by the licensing boards.

As improvements in entrance requirements, teaching facilities and qualifications of teachers have been made in medical schools, corresponding advances in educational requirements have been adopted by the majority of licensing boards. Since 1908, for example, the requirement of two years of college work in addition to a high school course has been adopted by thirty-nine states.[1] Thus, the licensing boards are supporting the better medical schools in the enforcement of this requirement. Again, since 1914, the number of states refusing recognition to seriously inferior medical schools has increased from fourteen to forty-eight of the fifty states, counting Alaska and the District of Columbia.[2] In the majority of states, therefore, so far as the licensing of physicians and surgeons is concerned, the public is well protected against incompetent physicians. The public is still at the mercy of improperly trained and incompetent practitioners being turned out by the various "schools" of healers bordering on medicine, some of whom have been licensed in certain states against the advice of the medical profession.

DIFFERING STANDARDS OF LICENSURE ILLOGICAL

The medical licensing boards of all states now require of physicians a reasonably high standard of educational and professional qualifications. The minimum standard consists of a high school education; two years of college work; four years of study in a properly established medical school—including a training in the fundamental medical sciences and the practical application of this knowledge by the student in the examination and care of patients in dispensaries and hospitals—and a year's internship in a general hospital, where the student assumes a greater responsibility in the care of the sick while still under the supervision of the hospital staff. If this minimum requirement for training is considered as essential for physicians, a corollary is that no lower standard of education and training should be permitted for any groups of healers who also assume responsibility for the lives of sick or injured people. The legality of a single but reasonably high standard of qualification for all who are to practice the healing art was splendidly set forth two years ago by Harry Eugene Kelly, a Chicago attorney, in an article on "Regulation of Physicians by Law."[3] The adoption of a single standard therein advocated is the only way to safeguard the public against ignorance, bungling and incompetence on the part of those who are licensed to practice medicine.

STATE HOUSE-CLEANINGS IN LICENSURE

During the last three years, Connecticut has been engaged in cleaning up the serious mess caused by the Eclectic Board of Medical Examiners in the licensing of 167 "graduates" of inferior colleges and diploma mills. Since this cleansing process began, the number of such candidates licensed each year decreased from seventy-four in 1922 to none in 1924. During 1925, in spite of the evidence brought out in regard to the fraudulent character of two diploma mills, the Eclectic Board of Connecticut, which is controlled by the debarred eclectic physicians, examined and certified for license another "graduate" of one of those institutions. The license was refused, however, by the health

John G. Bowman, Dr. Eugene L. Opie, Dr. Lewis A. Conner, Dr. J. M. T. Finney, Dr. W. S. Leathers, Dr. O. H. Perry Pepper, Dr. J. Whitridge Williams and Dr. Howard T. Karsner. The secretary-treasurer is Dr. J. S. Rodman, and the managing director is Mr. E. S. Elwood.

Up to Dec. 31, 1921, eleven examinations had been held, as follows:

Date of Examination	Where Held	Total Examined	Passed	Failed	Percentage Failed
Oct., 1916	Washington	10	5	5	50.0
June, 1917	Washington	12	9	3	33 3
Oct., 1917	Chicago	28	22	6	21.5
Jan., 1918	New York	20	18	2	10.0
Apr., 1918	Ft. Riley, Ft. Oglethorpe	23	18	5	26.1
Dec., 1918	Chicago, New York	16	15	1	6.3
June, 1919	Philadelphia	52	51	1	1.9
Feb., 1920	Chicago, St. Louis	48	36	12	25.0
May, 1920	Philadelphia	60	46	14	23 3
Feb., 1921	Rochester, Minn	16	11	5	31.3
June, 1921	Boston	40	37	3	7.5
	Totals	325	268	57	14.4

Following the completion of each examination shown in the table, those who passed were granted the board's certificate, a total by Dec. 31, 1921, of 268.

NEW METHODS ADOPTED

In 1922, however, the examinations were divided in three parts, as follows: Part I, a written examination in the six fundamental medical sciences: anatomy, including histology and embryology; physiology, physiologic chemistry; general pathology; bacteriology; materia medica and pharmacology. Part II, a written examination in: medicine, including pediatrics, neuropsychiatry and therapeutics; surgery, including applied anatomy, surgical pathology and surgical specialties; obstetrics and gynecology; public health, including hygiene, and medical jurisprudence. Part III, a practical examination in each of the following four subjects: (*a*) clinical medicine, including medical pathology, applied physiology, clinical chemistry, clinical microscopy and dermatology; (*b*) clinical surgery, including applied anatomy, surgical pathology, operative surgery and the surgical specialties of the diseases of the eye, ear, nose and throat; (*c*) obstetrics and gynecology; (*d*) public health, including sanitary bacteriology and the communicable diseases.

Parts I and II are written examinations held in any class A medical school, and part III is an entirely practical and clinical examination given by subsidiary boards in Boston, New York, Philadelphia, Minneapolis, Iowa City, San Francisco, Denver, New Orleans, Baltimore, Galveston, Cleveland, St. Louis, Chicago, Washington, Portland (Ore.), and Nashville. The fees are as follows: registration fee, $5; part I, $10; part II, $15; part III, $50.

EXAMINATIONS IN PART I

Three examinations in part I were held in 1925, as follows:

Date of Examination	Total Examined	Passed	In complete	Failed	Percentage Failed
February, 1925	143	116	6	21	14.7
June, 1925	324	205	31	88	27.2
September, 1925	141	79	13	49	34.8
Totals, 1925	608	400	50	158	26.0
1924	591	415	69	107	18.1
1923	507	349	77	81	16 2
1922	388	263	58	67	17.3
Totals	2,094	1,427	254	413	19.7

Altogether, 608 candidates were examined in 1925, as compared with 591 in 1924, 507 in 1923 and 388 in 1922. During the last four years, under the new plan, 2,094 candidates were examined, or more than six times as many as were examined in the six years of the old plan—from 1916 to 1921. Of all those examined in part I during the last four years, 413, or 19.7 per cent, failed.

EXAMINATIONS IN PART II

Three examinations in part II were held in 1925, as follows:

Date of Examination	Total Examined	Passed	In complete	Failed	Percentage Failed
February, 1925	84	74	...	10	11.9
June, 1925	167	151	...	16	9.6
September, 1925	91	84	...	7	7.7
Totals, 1925	342	309	...	33	9.6
1924	267	227	...	40	14.9
1923	192	170	2	20	10.4
1922	109	90	...	19	17.4
Totals	910	796	2	112	12.3

During 1925, 342 candidates were examined in part II, as compared with 267 in 1924, 192 in 1923 and 109 in 1922. Altogether, 910 candidates were examined during the four years, of whom 112, or 12.3 per cent, failed.

EXAMINATIONS IN PART III

The examinations in part III in 1925, which were entirely clinical and practical, were held in several of sixteen subsidiary centers in different parts of the country. The results of the examinations were as follows:

Examinations of	Total Examined	Passed	Failed	Percentage Failed
1922	28	28	..	0.0
1923	76	75	1	1.3
1924	120	114	6	5.0
1925	217	206	11	4.1
Totals	441	423	18	4.1

In 1925, 217 candidates were examined in part III, as compared with 120 in 1924, seventy-six in 1923 and twenty-eight in 1922. During the four years, therefore, 441 candidates were given the final practical examination and, of these, eighteen, or 4.1 per cent, failed.

Total Individuals Examined During Three Years

Year	Parts I, II and III, Excluding Duplications				
	Examined	Passed	Incomplete	Failed	Percentage Failed
1922	525	381	58	86	16.4
1923	775	594	79	102	13.4
1924	978	756	69	153	15.6
1925	1,167	915	50	202	17.3
Totals	3,445	2,646	256	543	15.8

Omitting duplicates, there were 1,167 individuals who took the National Board's examinations during 1925, as compared with 978 in 1924, 775 in 1923, and 525 in 1922. The percentage of failures was 17.3.

IN GENERAL

Of the failures, it is noted that during the last four years, 19.7 per cent of the candidates failed in part I, 12.3 per cent of the candidates failed in part II, and 4.1 per cent of the candidates failed in part III. Altogether, 3,445 candidates participated in the National Board's examinations during the four years since Jan. 1, 1922, and of these, 543, or 15.8 per cent, failed.

Of those who took examinations in parts I and II during the four years, 256 are listed as incomplete. These are candidates who took examinations in all but one of the subjects included in parts I and II and are listed as incomplete until they have taken an examination also in the remaining subject. In the statistics, however, although mentioned separately, they are counted as successes and not failures.

RECOGNITION OF THE NATIONAL BOARD'S CERTIFICATES

Holders of certificates from the National Board of Medical Examiners are registered without further examination in thirty-two states, the Canal Zone, Porto Rico and Hawaii.

come in contact with foods or drinks, especially if they contain acids of any sort, because it is readily dissolved by many of them. This would exclude its use for cooking utensils of any sort, for shakers of cocktails and acid drinks, and for the worms of the condensers in stills. Copper has joined the company of lead, mercury, zinc, arsenic, carbon monoxide, methyl alcohol, and noxious war gases to worry the ranks of the peaceful citizen who only a few years ago could safely be left in complete oblivion of the existence of such hazardous chemical substances.

THE HEMOLYTIC CONSTITUTION

The manifestations of disease are the products of two factors, the patient's own make-up or attributes, and forces from the outside. Much has been done toward elucidating the outside factor, the infections, physical injuries and chemical injuries that are the immediate cause of disease. However, the existence of the individual factor, the special susceptibility to certain affections, has also been recognized at all times, usually under the name of a diathesis of this or that sort. This conception is gaining in importance at present, especially in the field of pediatrics, where different types of children with special predispositions are recognized. The same is true of adults, who also appear to have their tendencies toward particular diseases and their points of special weakness.

Draper, in his book "The Human Constitution," defines constitution as the "aggregate of hereditarial characters, influenced more or less by environment, which determines the individual's reaction, successful or unsuccessful, to the stress of environment." Among these hereditarial characters, Gänsslen[1] and his co-workers place the tendency to increased blood destruction, which may become manifest, depending on the outside influences to which the individual is exposed, as hemolytic icterus. After several years of study of this condition, Gänsslen finds that one can speak of a definite "hemolytic constitution," characterized by congenital increased blood destruction, and manifested in fully developed cases by anemia, icterus and enlargement of the spleen. On investigating the families of persons with these symptoms, he found many instances of the condition, either latent or in active form. In fact, hemolytic icterus is a much more frequent disease than is commonly thought. The frequent lack of definite and active symptoms enables its presence to escape notice.

In its complete development, the disease is manifested by icterus, anemia, enlargement of the liver and spleen, and urobilinuria; with decreased resistance of the erythrocytes, anisocytosis and microcytosis. The icterus is variable in degree, as is the anemia. Both are increased during the so-called hemolytic crises. These are frequently evoked by some intercurrent factor, infections, pregnancy or psychic causes, which provide the occasion for the hitherto latent condition to become active. The crises are often accompanied by colicky pains over the liver and spleen, and, with the icterus, may be taken for gallbladder disease. The hemoglobin is ordinarily from 40 to 70 per cent, but may fall during a crisis to 20 per cent. Examination of the red blood cells reveals the essential nature of the disease: anisocytosis and microcytosis indicate an inferior quality of the cells, which is further shown by their increased fragility in salt solution. These changes vary considerably in degree, but there is close agreement between the abnormality of form and decrease in resistance. Gansslen regards this as the fundamental condition. The icterus and anemia are secondary consequences of the increased blood destruction, when it is no longer compensated by increased formation and the liver is no longer able to cope with the increased iron metabolism. The subjective symptoms are few; if one may quote the oft-cited words of Chauffard, the patients are more yellow than sick.

According to Gansslen, the types, or really degrees, of the hemolytic constitution range from the complete disease picture to the latent form, which is entirely symptomless, and detected only by blood examination and investigation of other members of the family. Compensated forms occur, in which one or more of the chief symptoms are lacking. Thus, among Gänsslen's cases there were 35 per cent without anemia, 40 per cent without icterus, 30 per cent without enlargement of the spleen, and 10 per cent without definite lessening of the resistance. Then there is a group of mildly affected persons, symptomless, with slight or even no change in the red cells, who transmit the hemolytic constitution to their offspring. Recognition of all these incomplete and latent forms is based on suggestive symptoms, usually some change in the red cells, and occurrence of the condition, often in more complete form, in other members of the family. The latent types, given the proper stimulus from the outside, may become active at any time.

An interesting point, emphasized by Gänsslen and demonstrated in many of his cases, is the frequent combination of other congenital anomalies with the hemolytic constitution. Anomalies of the skull, tower skull and negroid shape, are especially frequent; also polydactylia, microphthalmia, epicanthus, amblyopia, deformities of the ear, and congenital heart lesions. Combinations with endocrine disturbances also occur. This association with congenital defects may help in making the diagnosis of familial hemolytic icterus, and is of course an additional argument for its constitutional character.

One extensive family tree investigated by Gänsslen comprised six generations and 169 persons. Of these, commissioner of Connecticut, and mandamus proceedings were resorted to. The decision will soon be rendered. In Missouri, also, a new licensing board has been established; the two medical schools in that state have been prosecuted, and conditions in licensure have been much improved. Whether the charters of the two diploma mills are to be revoked is to be decided by the Missouri Supreme Court. One of these mills, the Kansas City College of Medicine and Surgery, in spite of the legal proceedings, issued diplomas to four "graduates" during 1925, to whom the Arkansas Eclectic Board promptly granted licenses—as well as to fifteen other graduates of this school whose diplomas bore earlier dates. It is evident, therefore, that a vigorous house-cleaning in licensure is much needed in Arkansas also.

NEED OF FURTHER PUBLICITY

The protection of the public in regard to the menace from sectarians of various types depends mainly on publicity. State regulations are based on public sentiment, which thus far has been formulated largely by the selfish and misleading clamor of sectarian groups. It is important, therefore, that a wider publicity be given to the established and reliable facts regarding modern medicine and the benefits obtainable from the improved methods of diagnosis and treatment. Indeed, it is believed that public sentiment is now turning rapidly to the truths of scientific medicine.

From the standpoint of medical licensure, the solution of the problem is simple: Secure in each state one medical practice law establishing a reasonably high standard of educational and professional qualifications which should be possessed by every one who is to secure the legal right to practice the healing art, and a competent board of medical examiners to carry out the provisions of the law.

"HOOCH," "HOME BREW" AND COPPER

The toxicity of many of the heavy metals has been known for generations, yet these substances have not been regarded as a menace to human health except in limited instances where industrial conditions or occupational circumstances exposed workers to the chemical hazards in some uncommon way. However much the student of vocational diseases might become concerned with the effects of metallic poisons, the treatises on public health and personal hygiene rarely discuss them except in a casual manner. As a consequence of modern economic and social changes, the latent dangers of poisoning from certain heavy metals are now suddenly presented to the public at large. To gasoline and the automobile we owe the nation-wide concern about lead;[1] suicides and syphilis have awakened a new interest in mercury not merely as a drug but also as a poison; and now the advent of the "bootlegger" and home brew has brought copper to our toxicologic attention.

In his Mellon Lecture at Pittsburgh, Mallory[2] of Boston pointed out that we are constantly exposed to the action of copper. The fact that our organs on chemical examination yield a certain amount of it does not mean that copper is a normal and necessary component of the body but that we cannot get away from it. This does not mean, Mallory adds, that we are all suffering from copper poisoning. It seems perfectly evident that we can handle a certain amount of the metal without danger, perhaps from 5 to 10 mg. a day, possibly more. The only visible effect may be the presence of a little hemofuscin in fibroblasts in the liver and some of the other organs where it cannot be transformed into hemosiderin and then be gradually dissolved and removed. If, however, the amount absorbed exceeds a certain definite limit, the danger of pigmentation of the liver and pancreas is evident. Mallory sees the evidence slowly but steadily accumulating in favor of the view that chronic poisoning with copper causes the symptom complex known under the different names of hemochromatosis, bronzed diabetes and pigment cirrhosis. As if it were not damaging enough to the reputation of alcohol to be charged directly with being a possible cause of hemochromatosis, chemists have demonstrated that present-day distilled liquors may contain as much as 185 mg. of copper per liter. It is reported that the director of the division of foods and drugs of the department of public health of Massachusetts has tested 798 samples of "hooch" and found copper present from a trace up to 32 mg. to the liter in 10.8 per cent. Samples of even "home brew" have been found on chemical examination to show the presence of 25 mg. of copper to the liter. The introduction of the metal is not to be attributed to malicious intent but rather to the action of organic acids in the mash distilling over with the alcohol and acting on the copper worm of the condenser when that metal is used. Mallory states that cocktail shakers are usually made of copper or brass and lined with silver or tin. When the latter metals are worn or dissolved off, the acids, for example, citric, in the ingredients readily attack the copper. The shakers used at soda water fountains for mixing lemonades are usually made of copper. It would be manifestly unjust to imply that alcoholic beverages provide the only likely sources of copper that man may ingest. Copper pots and kettles, copper and brass pipes, find use in culinary practices or the experiences of everyday life.

Mallory's advice seems wholesome: Copper is an exceedingly useful and indispensable metal in many ways, but it should not be employed where it may come in contact with foods or drinks, especially if they contain acids of any sort, because it is readily dissolved by many of them. This would exclude its use for cooking utensils of any sort, for shakers of cocktails and acid drinks, and for the worms of the condensers in stills. Copper has joined the company of lead, mercury, zinc, arsenic, carbon monoxide, methyl alcohol, and noxious war gases to worry the ranks of the peaceful citizen who only a few years ago could safely be left in complete oblivion of the existence of such hazardous chemical substances.

THE HEMOLYTIC CONSTITUTION

The manifestations of disease are the products of two factors, the patient's own make-up or attributes, and forces from the outside. Much has been done toward elucidating the outside factor, the infections, physical injuries and chemical injuries that are the immediate cause of disease. However, the existence of the individual factor, the special susceptibility to certain affections, has also been recognized at all times, usually under the name of a diathesis of this or that sort. This conception is gaining in importance at present, especially in the field of pediatrics, where different types of children with special predispositions are recognized. The same is true of adults, who also appear to have their tendencies toward particular diseases and their points of special weakness.

Draper, in his book "The Human Constitution," defines constitution as the "aggregate of hereditarial characters, influenced more or less by environment, which determines the individual's reaction, successful or unsuccessful, to the stress of environment." Among these hereditarial characters, Gänsslen[1] and his coworkers place the tendency to increased blood destruction, which may become manifest, depending on the outside influences to which the individual is exposed, as hemolytic icterus. After several years of study of this condition, Gänsslen finds that one can speak of a definite "hemolytic constitution," characterized by congenital increased blood destruction, and manifested in fully developed cases by anemia, icterus and enlargement of the spleen. On investigating the families of persons with these symptoms, he found many instances of the condition, either latent or in active form. In fact, hemolytic icterus is a much more frequent disease than is commonly thought. The frequent lack of definite and active symptoms enables its presence to escape notice.

In its complete development, the disease is manifested by icterus, anemia, enlargement of the liver and spleen, and urobilinuria; with decreased resistance of the erythrocytes, anisocytosis and microcytosis. The icterus is variable in degree, as is the anemia. Both are increased during the so-called hemolytic crises. These are frequently evoked by some intercurrent factor, infections, pregnancy or psychic causes, which provide the occasion for the hitherto latent condition to become active. The crises are often accompanied by colicky pains over the liver and spleen, and, with the icterus, may be taken for gallbladder disease. The hemoglobin is ordinarily from 40 to 70 per cent, but may fall during a crisis to 20 per cent. Examination of the red blood cells reveals the essential nature of the disease: anisocytosis and microcytosis indicate an inferior quality of the cells, which is further shown by their increased fragility in salt solution. These changes vary considerably in degree, but there is close agreement between the abnormality of form and decrease in resistance. Gänsslen regards this as the fundamental condition. The icterus and anemia are secondary consequences of the increased blood destruction, when it is no longer compensated by increased formation and the liver is no longer able to cope with the increased iron metabolism. The subjective symptoms are few; if one may quote the oft-cited words of Chauffard, the patients are more yellow than sick.

According to Gänsslen, the types, or really degrees, of the hemolytic constitution range from the complete disease picture to the latent form, which is entirely symptomless, and detected only by blood examination and investigation of other members of the family. Compensated forms occur, in which one or more of the chief symptoms are lacking. Thus, among Gänsslen's cases there were 35 per cent without anemia, 40 per cent without icterus, 30 per cent without enlargement of the spleen, and 10 per cent without definite lessening of the resistance. Then there is a group of mildly affected persons, symptomless, with slight or even no change in the red cells, who transmit the hemolytic constitution to their offspring. Recognition of all these incomplete and latent forms is based on suggestive symptoms, usually some change in the red cells, and occurrence of the condition, often in more complete form, in other members of the family. The latent types, given the proper stimulus from the outside, may become active at any time.

An interesting point, emphasized by Gänsslen and demonstrated in many of his cases, is the frequent combination of other congenital anomalies with the hemolytic constitution. Anomalies of the skull, tower skull and negroid shape, are especially frequent; also polydactylia, microphthalmia, epicanthus, amblyopia, deformities of the ear, and congenital heart lesions. Combinations with endocrine disturbances also occur. This association with congenital defects may help in making the diagnosis of familial hemolytic icterus, and is of course an additional argument for its constitutional character.

One extensive family tree investigated by Gänsslen comprised six generations and 169 persons. Of these, as far as could be determined, eleven had fully developed hemolytic icterus; thirty-three had compensated cases; there were thirteen mild cases; and twenty-six persons, including many of those with hemolytic symptoms, had anomalies of the skull. He finds that hemolytic icterus is inherited as a dominant character, although it sometimes appears to be recessive on account of the frequent latent form, and appears in and is transmitted by both males and females.

[1] Gänsslen, M.; Zipperlen, E., and Schüz, E.: Die hämolytische Konstitution, Deutsches Arch. f. klin. Med. **146**: 1, 1925. Gänsslen: Ueber hamolytischen Ikterus, ibid. **140**: 195, 1922.

Nothing much need be done for the mild or latent cases of this disease. Splenectomy usually is advised for all young persons with high grade anemia or severe hemolytic crises. While not often fatal in itself, early deaths are rather frequent among persons with hemolytic icterus. The mortality of the operation is low, and the beneficial effects on the symptoms and general condition are often astounding. The anemia and icterus usually disappear entirely, although the changes in form and resistance of the red cells may remain. A return of the icterus after removal of the spleen, incident to some intercurrent infection, has been noted, and this fact furnishes additional evidence that hemolytic icterus is primarily a disease of the blood cells, and is not due to overactivity of the spleen.

Current Comment

LICENSING OF FOREIGN PHYSICIANS

Heretofore physicians from abroad have always been welcomed by licensing boards in this country, and in most states the requirements, if different at all, were less strict than for graduates of our own American schools. In this connection, physicians coming from Canada have hardly been considered as foreigners. Their qualifications are as clearly recognized as those coming from medical schools of the United States. This is because Canadian physicians have had their part in the movement instigated by the medical profession of this country to improve the standards of medical education and licensure. Many of the physicians who came from abroad, also, have long since become honored members of the communities in which they reside and are mostly active members of our medical organizations. Even at this time, therefore, there is no desire to establish unreasonable restrictions against foreign physicians, especially those who are bona fide graduates of well recognized medical schools and who come from countries whose laws, customs and manners of living are similar to those of the United States. Since the World War, however, a necessity for reasonable restrictions has developed. The numbers of physicians seeking licensure in this country have been increasing, as a result largely of the financial stress in their own countries from which they are endeavoring to escape. Among these there has been an unusual proportion whose credentials were of doubtful validity or distinctly fraudulent. It has become necessary for state authorities to establish legal safeguards over the admission of physicians from abroad. The requirement of American citizenship as an essential for the license has been adopted in eleven states;[1] in ten other states[2] foreign physicians must have taken out their first naturalization papers before being eligible for a license, and in five states[3] foreign physicians must have declared their intention to become American citizens. In Michigan and New York, in uncertain cases, a year's work in a medical school in this country must have been completed, while in Pennsylvania the foreign physician is required to have completed an internship in a hospital recognized by the licensing board. These regulations, although representing a change of attitude on the part of state licensing boards, are still much more lenient than the requirements in countries abroad with which American physicians must comply. There is still the desire to welcome from abroad those who are properly qualified and who will become reputable and worthy members of their communities. The restrictions are necessary, however, to prevent the inpouring of those who are not properly qualified or who in other respects are undesirable. Under no circumstances should physicians from abroad be accepted unless their credentials have been carefully verified and unquestionable proofs obtained of identity.

ARKANSAS STILL INACTIVE

Arkansas is one of the two remaining states that have separate boards of eclectic medical examiners. In the last ten years this board has licensed 227 graduates of inferior medical schools, of whom 199 held degrees from the Kansas City College of Medicine and Surgery—exposed two years ago as a diploma mill—for which legal proceedings looking toward the revocation of its charter are now in process. Following the exposure of the Missouri diploma mill ring, vigorous legal measures were promptly and successfully taken in Connecticut, California and other states toward revoking the licenses of those registered on the basis of such diplomas. Arkansas, however, has continued inactive in spite of the odium resting on the character of such applicants. In spite of the glaring disclosure of the Kansas City College of Medicine and Surgery as a diploma mill, the eclectic board has calmly continued to provide state licenses for such "graduates"! Although only one such graduate was licensed in 1924, this was evidently due not to any qualms of conscience on the part of the board but to the temporary inactivity of the diploma mill concerned because of the court investigation. Is it not time that Arkansas should undergo a house cleaning? Is it content to remain in the clutches of Alexander and his diploma venders? Is Arkansas satisfied to have its sick and injured citizens subjected to such ignorance, incompetence and bungling?

Education of Spartan Women.—Not much is known of the training imposed on the Spartan girls; but it included both gymnastics and music.—Leonard: History of Physical Education, pp. 19-20.

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

ALABAMA

Sanitation in Mining Towns.—A survey of mining towns in Alabama made by the U. S. Bureau of Mines, cooperating with the U. S. Public Health Service, indicates that sanitation in these towns receives more consideration than in most of the other coal fields of the country. At one time, communicable diseases in these communities made it necessary to employ 165 men in order to keep 100 men working, and mines occasionally were forced to shut down until an epidemic passed. This led the larger mining companies to install health departments, and health conditions have improved; in the last few years, there has been a decrease of thirty-five men per hundred necessary to keep 100 men working, and no epidemic has closed any mines in the state. The state board of health through county health units cooperates in this work; schools are inspected by camp physicians and the county health officers, when available. It is still difficult in mining towns where employees own their own homes to maintain sanitation. The sanitary rating of the towns covered by the survey varied from 43.75 to 95.50, and averaged 69.32. The water supply had the best rating of all the features; sewage disposal had a rating of about 50 per cent of the normal, and the rating on general sanitation was fair. Only the very small mines in Alabama are not actively engaged in sanitary work now, and while they assert that they are not financially able to maintain health departments, they have adopted many of the methods put into operation by the larger mining companies.

ARIZONA

State Medical Election.—At the recent annual meeting of the Arizona State Medical Association at Globe, April 26-28, Dr. Charles S. Vivian, Phoenix, was elected president elect; Drs. Arthur C. Carlson, Jerome, Hilary D. Ketcherside, Yuma, and Harold W. Rice, Morenci, vice presidents; Dr. Clarence E. Yount, Prescott, treasurer, reelected, and Dr. Delamere F. Harbridge, Phoenix, secretary (reelected for the tenth time). The next meeting will be at Yuma in April, 1927.

CALIFORNIA

State Medical Election.—At the recent annual meeting of the California Medical Association, Oakland, April 26, Dr. William T. McArthur, Los Angeles, was elected president; Dr. Percy T. Phillips, Santa Cruz, president-elect; Dr. Robert V. Day, Los Angeles, vice president, and Dr. Emma W. Pope, San Francisco, secretary.

Hospital News.—The Children's Hospital, San Francisco, will build this year a wing costing about $350,000 for a maternity department and physiotherapy department.——The new Providence Hospital, which is being erected at Central Avenue and Thirtieth Street, Oakland, is expected to be completed not later than July; it will have a total capacity of 350 beds.

Japanese Quack Fined.—A Japanese, one A. Nemoto of East San Pedro, was arrested, February 15, charged with violating the state medical practice act. Nemoto claimed to be a graduate of medicine of Tokyo University and had been located in East San Pedro more than a year. His reception room was an innocent appearing place with nothing to indicate that it was a doctor's office, but when Nemoto was forced to unlock the adjoining room, after he had assured the authorities that he was not practicing medicine and that the room was not his, a completely equipped doctor's office was found. It contained operating tables, surgical instruments, sterilizers, hypodermic needles, a large supply of medicines and record slips, indicating that Nemoto had treated a number of Japanese patients. When arraigned, Nemoto pleaded guilty and stated that he had assembled the equipment to use in Mexico, where he said he was arranging to go; he said further that he had treated a few of his friends, not knowing that he was violating the law. He was sentenced to pay a fine of $100 or serve a hundred days in jail. He paid the fine.

COLORADO

Dr. Mills Resigns.—Dr. Ralph G. Mills, professor and head of the department of pathology, University of Colorado School of Medicine, Denver, has resigned to accept a position on the permanent staff in pathology of the Mayo Clinic, Rochester, Minn., which carries with it a full professorship in pathology at the University of Minnesota. Dr. Mills will take up his work in Rochester before July 1.

CONNECTICUT

Meaning of Certified Oysters.—The state department of health says that a certificate is not a guarantee of each particular shipment of oysters, but that all desirable safeguards have been taken to insure that the public is receiving a safe product. Certification in Connecticut means that: (1) the dealer agrees to ship oysters only from areas which have been inspected and analyzed by the state department of health and which have been found to be satisfactorily located; (2) the shucking and packing establishment has been inspected and found in a sanitary and satisfactory condition, and (3) all persons in the establishment engaged in shucking, handling and packing oysters have been examined and found free from typhoid bacilli.

GEORGIA

Hospital News.—The new Blackman Health Resort, 1824 Peachtree Road, Atlanta, succeeding the Blackman Sanatorium at 172 Capitol Avenue, was opened, March 29.——Dr. Joe R. Clemmons has been appointed superintendent of the Macon Hospital, Macon, effective, May 1.

Personal.—Dr. Charles L. Ridley, city-county health officer at Macon, resigned, May 1, to become the chief medical director of the Bankers' Health and Life Insurance Company.——Dr. John W. Oden, for eight years on the staff of the Georgia State Sanitarium, Milledgeville, has resigned to accept a position with the Children's Hospital for the Feeble Minded in Augusta.——Dr. John M. T. Finney, Baltimore, was recently the guest of the Richmond County Medical Society.

ILLINOIS

Dr. Krafft Honored.—The meeting of the Physicians' Fellowship Club, Chicago, May 7, was held in honor of Dr. Jacob C. Krafft, president of the Illinois State Medical Society. Among those who rendered tribute to Dr. Krafft's service to medicine in Illinois were Drs. Edward H. Ochsner, John R. Neal, Harold M. Camp, James W. Vanderslice, Jeremiah H. Walsh and William D. Chapman.

Personal.—Dr. Placid N. Chiasson, Griggsville, has been elected president of the Pike County Medical Society; Dr. William Shastid, secretary and treasurer of the society for the last twelve years, retired, and Dr. Frank N. Wells, Pittsfield, was elected secretary-treasurer.——Dr. Charles Lieber, Waukegan, has been reappointed county physician of Lake County.——Dr. Edward A. Glasgow, Mulberry Grove, has been reelected president of the Bond County Medical Society and Dr. Thomas G. Charles, Beardstown, has been elected president of the Cass County Medical Society.

Society News.—The Golden Anniversary of the Central Illinois Medical Society was celebrated at Pana, April 27. Dr. John H. Miller, Pana, gave an address on "The Early History of the District Medical Society of Illinois." Clinics were held at the Huber Memorial Hospital. Dr. Arthur O. Fisher, associate in clinical surgery, Washington University Medical School, St. Louis, gave an illustrated lecture on "Recent Aids in the Diagnosis of Gallbladder Diseases and Other Abdominal Conditions," and Dr. Llewellyn Sale, St. Louis, spoke on "Tests for Liver Function"; Dr. Theodore Thompson, Shelbyville, was elected president of the society; Dr. Jesse P. Simpson, Palmer, vice president, and Dr. Franklin A. Martin, Pana, secretary-treasurer.

Counties Having Highest Tuberculosis Mortality.—Union County and the contiguous counties of Pulaski and Alexander in the southern part of the state comprised the area of heaviest tuberculosis mortality last year, according to the state health director; Union County had a mortality rate of 296 per hundred thousand population, and Pulaski and Alexander counties, 239 and 154, respectively. The area of lightest tuberculosis mortality comprised Woodford, Marshall and Carroll counties in the northern part of the state, where the rates were 10.20 and 20.5, respectively. Among the forty-four cities of 10,000 or the highest mortality rate from tuberculosis (276) was reported from Lincoln; then came Jacksonville (208); then Cairo (200); Ottawa had the lowest municipal rate (26); then came Rockford (32); then Streator (33).

Chicago

University News.—Dr. David J. Davis gave the last of the series of lectures on the history of medicine at the University of Illinois College of Medicine, April 21; his subject was "Contributions Which the Quakers Have Made to Medicine."

Cooperation Among Medical Libraries.—Representatives of the larger medical libraries of Chicago met, May 8, to discuss the medical library situation of that city with a view to working out some form of cooperation whereby the duplication of expensive and rarely used material may be avoided and such material be made mutually accessible. As a preliminary to such action, it seemed necessary to agree on some outline of the scope of the various libraries. Those present were impressed with the importance of such cooperation and the benefits that might be expected in the expenditure of available funds as well as in the general administration of the several libraries. Dr. William F. Petersen, professor of general medicine, University of Illinois College of Medicine, was appointed chairman of a committee to work out some definite form of coordination.

Hospital News.—The Garfield Park Hospital is planning a $690,000 building to be constructed on the site of the present nurses' home. St. Anne's Hospital is drawing plans for a 250 bed addition which will cost about $800,000.——The University of Chicago has been bequeathed $500,000 by the will of Mrs. Harriet Smith for the construction of a contagious disease hospital to be known as The Charles Gilman Smith Hospital.——The Albert Billings Memorial Hospital group at the University of Chicago will be turned over for operation about Jan. 1, 1927.——Construction work was started, May 3, on the new six story Rogers Park Hospital at 6970 North Clark Street, the capacity of which will be 102 beds. Dr. F. Patrick Machler, formerly superintendent of the Iroquois Hospital, is president of the organization.——A $275,000 medical office building is being erected on the West Side at Madison Street and Kilbourn Avenue, which is being financed by the West Town State Bank. There will be forty offices for physicians and dentists.

INDIANA

Hospital News.—The board of trustees of the Methodist Hospital has authorized the expenditure of $850,000 to improve the Methodist hospitals at Indianapolis and Gary.——A banquet was tendered, April 8, to members of the Laporte County Medical Society and many other physicians in the surrounding cities to celebrate the formal opening and dedication of the new Clinic Hospital Building at Fifth and Pine streets, Michigan City. Dr. Burton Hazeltine, Chicago, was toastmaster, and the principal speaker was Dr. Charles B. Reed, formerly professor of obstetrics at Northwestern University Medical School, Chicago.

Personal.—Dr. Harvey H. Martin, Laporte, was elected president of the Northern Tri-State Medical Association (Ohio, Indiana, Michigan) at the recent meeting in Lima, Ohio.——Dr. C. M. White celebrated the completion of his fiftieth year in medical practice at Clinton, March 11.——Dr. Charles H. DeWitt, Valparaiso, has been appointed health officer of Porter County.——The governor has reappointed Dr. William A. Spurgeon, Muncie, and Dr. Jesse W. Bowers, Fort Wayne, members of the state board of medical registration for terms of four years.——Drs. Eli L. Youngblood and Paul E. Wilson have been appointed members of the board of health of Boonville.

KANSAS

State Medical Meeting.—The visiting guests at the sixtieth annual meeting of the Kansas Medical Society, Kansas City, May 4-6, included Dr. John M. Dodson, Chicago, former dean of Rush Medical College, who spoke on "Medical and Health Education of the Laity"; Dr. Harry C. Goodson, Colorado Springs, "General and Local Rest in the Treatment of Pulmonary Tuberculosis"; Dr. Jacob P. Greenhill, Chicago, "Management of the Second Stage of Labor"; Dr. George C. Mosher, Kansas City, Mo., "The Campaign for Better Obstetrics"; Dr. Hiram Winnett Orr, Lincoln, Neb., "Fractures", and Dr. Warren H. Cole, St. Louis, "Gallbladder Research Work."

KENTUCKY

Miscellaneous Items.—The health officer of Charlestown closed the schools of that community, April 22, it is reported, because of an outbreak of five cases of smallpox among the pupils; graduating exercises were to have been held in the high school the following day.——Dr. Ralph Holt, Grahamville, has been elected county physician of McCracken county for four years, to succeed Dr. Louis E. Young, Milan.——Construction work has started on the new Deaconess Hospital at Clifton Avenue and Straight Street, Covington.——The Good Samaritan Hospital, Lexington, has let the contracts for a $300,000 four story addition to be erected on South Limestone Street.

Court Upholds Board of Health.—Judge Clay of the Court of Appeals, Frankfort, March 20, upheld the state board of health's ruling which requires that no person shall become a member of any public or private school within the jurisdiction of the board, either as a teacher or a pupil, without furnishing a certificate from a reputable physician that he has been successfully vaccinated, and has been revaccinated at least once every seven years. The judge overruled the motion of several persons from Ashland for a temporary injunction enjoining the Boyd County Board of Health, the health officer and school board of Ashland from enforcing this rule; he said that the state and local boards of health have the power when there is a reasonable apprehension of an epidemic of smallpox in the school to order vaccinations, and that the evidence in this case did not disclose any abuse, on the part of the defendants, of this discretion.

MARYLAND

State Medical Election.—At the one hundred and twenty-eighth annual meeting of the Medical and Chirurgical Faculty of Maryland, April 27-29, Baltimore, Dr. Thomas S. Cullen was elected president; Drs. John L. Riley, Snow Hill, Standish McCleary, Baltimore, and Frank W. Keating, Owings Mills, vice presidents; Dr. Joseph Albert Chatard, Baltimore, secretary, and Dr. Charles E. Brack, Baltimore, treasurer.

Child Health.—Sponsored by the American Child Health Association, a program to improve child health will be presented throughout the state during May; exercises have been held in the schools throughout the state to forward the program. Dr. James H. Mason Knox, Jr., of the state health department, is chairman of a committee of ninety who are endeavoring to obtain a wide-spread cooperation in carrying out the program.

University News.—Johns Hopkins University Medical School, Baltimore, has created the position of secretary, to which Lawrence H. Baker, Ph.D., has been appointed. Dr. Baker will also act as registrar of the medical school.——Dr. Horace Lo Grasso, superintendent, J. N. Adam Memorial Hospital, Perrysburg, N. Y., gave one of the De Lamar lectures at the Johns Hopkins University School of Hygiene and Public Health, April 12, on "Clinical Results of Heliotherapy."

Charles E. Dohme Lectures.—Dr. Walter Ernest Dixon, professor of materia medica and pharmacology, Kings College, University of London, delivered the fourth series of lectures of the Charles E. Dohme lectureship at the Johns Hopkins School of Hygiene and Public Health, May 7-10; the subjects were: (1) The Nature, Secretion and Circulation of the Cerebrospinal Fluid. The Influence of Drugs on the Secretion. (2) The Vascular System of the Brain and Its Comparison with That of the Pulmonary System. The Influence of Drugs on Cerebral Vessels. Shock. (3) The Pituitary Gland. The Influence of Pituitary, Alimentary and Ovarian Extracts. The Action of Pituitary Extracts on the Uterus.

Personal.—Dr. Charles C. Hedges, former health commissioner of Marshall County, W. Va., has assumed the duties of assistant director of the Johns Hopkins Hospital, succeeding A. W. Buck.——Dr. Worth B. Daniels, son of the former secretary of the navy, has been appointed an intern at Johns Hopkins Hospital; Dr. Daniels graduated from the medical school in 1924; Edmund B. Kelly and Christopher Johnston, senior students at the John Hopkins Medical School, have also received appointments as interns. Mr. Kelly is a son of Dr. Howard A. Kelly, and Mr. Johnston is the grandson of the late Dr. Christopher Johnston.——Dr. Wilfred T. Grenfell of the Grenfell Mission gave an illustrated lecture, April 26, at the Medical and Chirurgical Faculty Building, Baltimore, on "Missionary Work in Labrador."

MASSACHUSETTS

Research on Yaws—The Department of Tropical Medicine of Harvard University Medical School, Boston, and the Bureau of Science, Manila, P I, have been directing the expenditure of a fund provided by Mr H A Metz, New York, for the study and control of yaws (frambesia tropica) The work has been done in the Philippine Islands, where the government hospitals and laboratories of the bureau of science and the Philippine Health Service afford facilities for clinical and experimental study The results of about five years' work will be published in a forthcoming number of the Philippine Journal of Science

Personal—Dr Harvey Cushing, Harvard University Medical School, Boston, author of "The Life of Sir William Osler" was awarded the $1,000 prize for "the best American biography teaching patriotic and unselfish service to the people, illustrated by an eminent example,' by the judges of the Pulitzer prizes——Dr Morton Prince will take up the duties next September, of associate professor of abnormal and dynamic psychology in Harvard University, Dr Henry A Murray, Jr, has been appointed research fellow in abnormal and dynamic psychology and will work with Dr Prince, who formerly was clinical instructor in diseases of the nervous system at Harvard and professor of nervous diseases at Tufts College Medical School, Boston, from 1902 to 1912

MICHIGAN

Society News—The Michigan State Medical Society has planned three postgraduate conferences for May and early June, at Alpena, May 6 Fremont, May 11, and a third conference at Jackson——The county medical societies that have already arranged for or conducted a special meeting on periodic health examinations are St Clair, Washtenaw Alpena, Lenawee, Muskegon, Jackson, Houghton and the Tri-County Medical Society——Dr Alexander J MacKenzie Port Huron, addressed the St Clair County Medical Society, April 1, at Port Huron on "Infections of the Gallbladder Dr William H Marshall, Flint, addressed the society, April 15, on "Periodic Physical Examinations of the Apparently Healthy"——Dr Robert B. Preble, Chicago, addressed the Calhoun County Medical Society, April 6, on "Pneumococcus Pneumonia"——Dr Philip D Bourland, Calumet, addressed the Houghton County Medical Society, April 6, on "Clinical Value of the Electrocardiograph"——Dr Arthur C Tompsett, Hesperia, has been elected president of the Newaygo County Medical Society, and Dr. William H. Barnum, Fremont, secretary.

NEW HAMPSHIRE

Cancer Campaign.—The state committee of the American Society for the Control of Cancer, which met at Concord, April 16, under the chairmanship of Dr Fred E Clow, Wolfeboro, decided to launch a campaign of education throughout the state in October, and to ask the state medical society to assist in procuring funds from the legislature to build a hospital for incurables

Meeting of Surgical Club—At the twenty-eighth semiannual meeting of the New Hampshire Surgical Club, Nashua, April 27, Dr Frederick W. Johnson, chief, gynecologic service, Carney Hospital, Dr Donald Munro and Dr Arthur W Allen, all of Boston, conducted a clinic at St Joseph's Hospital, in the afternoon Dr John P Bowler, Hanover, gave an address on "Three Causes of Urinary Frequency," and Dr Fred S Eveleth, Concord, "The Value of Cholecystography", Dr James B Woodman, Franklin, president of the New Hampshire Surgical Club, presided, there were about 125 persons present, many of whom took part in the discussions

NEW YORK

Miscellaneous Items—Dr Benjamin Kramer, Brooklyn, addressed the Buffalo Academy of Medicine, April 28, on "Newer Aspects of the Etiology and Treatment of Infantile Tetany"——A modern health center has been established in Elizabethtown in Essex County through the efforts of the local health officer, Dr Alexander Gersen, and various organizations——Practically every child in Granville under 12 years of age has been immunized against diphtheria, according to *Health News*——The Montgomery County Medical Society at its first meeting this year adopted plans for children's consultation clinics throughout the county, and instructed its committee to complete arrangements for the clinics in each community

Personal—Dr Melville D Dickinson, Troy, has been appointed a district state health officer in the state department of health——Dr Clara H Pierce has been appointed physician in charge of the bureau of child hygiene of the department of health of Syracuse——The gold medal of the New York Rotary Club was awarded, April 18, to Mother M Alfonsa Lathrop, founder of the Servants of Relief for Incurable Cancer at Hawthorne, N Y, and daughter of Nathaniel Hawthorne, the novelist, for "outstanding service to humanity during the last year——Dr David Warshaw, Albany has been appointed chief of clinic and adjunct attending surgeon surgical outpatient department, Mount Sinai Hospital

New York City

Society Creates Relief Fund—The Yorkville Medical Society at its last meeting of the executive officers created a hospital relief fund to aid needy members of the society; a loan of $5 000 through the efforts of Dr Charles N Gelber, who is chairman of the committee, was advanced to start the fund

Chiropodist Fined—Samuel Marder, said to be a chiropodist, 155 St Marks Place, Manhattan, was fined $100 in court in Jamaica recently, it is reported, on a charge of practicing medicine illegally Marder is said to have attended a person complaining of abdominal distress, and to have sent a bill for attending the patient for a sprained ankle

New Kind of Clinic—The James Buchanan Brady Foundation, New York Hospital, announces the establishment this week of a clinic for the nonsurgical treatment of tuberculosis of the urinary tract which will be, it is said, the first of its kind in the United States Clinics for adults will be held Tuesday and Friday afternoons, from 2 to 4, and for children, Saturday mornings from 9 to 10 The Finsen light, the alpine light and tuberculin injections will play an important part in the treatment Dr Stanley L Wang will be in charge of the new clinic under the direction of Dr Oswald S Lowsley, head of the Brady Foundation

Prizes for Manuscripts on Public Health—The Harmon Foundation offers through the *Survey* prizes of $250, $100 and $50 for the best unpublished manuscripts dealing with some experiment invention or achievement in the field of public health The subject must be presented so as to be interesting to lay readers in not less than 1,000 words nor more than 2 500 words and be typewritten, double-spaced and delivered not later than June 30 to "The Jury, Harmon-Survey Award 3 care of the *Survey*, 112 East Nineteenth Street, New York There must be a pen name on the manuscript, accompanied by a plain, sealed envelop having on the outside the pen name, and within both the pen name and the real name of the author Dr Haven Emerson is chairman of the jury

Tuberculosis Death Rate Reduced.—There were 5,471 deaths from tuberculosis in the city during 1925, which was 116 fewer than in 1924, of these, 4,775 were of the pulmonary type A chart published by the New York Tuberculosis and Health Association shows a comparatively high plateau for tuberculosis deaths from 1898 to 1918, there was a decided drop in 1909 another in 1920, and another in 1921, then a much smaller decline down to the present The number of deaths in the city from all forms of tuberculosis in 1907, for example, was 10,262, in 1918, 10,098, in 1898 9,265 Almost half of the deaths from pulmonary tuberculosis last year occurred in Manhattan, the oldest and most crowded part of the city The average death rate from pulmonary tuberculosis for the city as a whole was 81 per hundred thousand, for Manhattan, it was 113 per hundred thousand, an excess of 40 per cent The death rate in the borough of Brooklyn was 63 per hundred thousand, which was 5 per cent less than it was the year before There were 10,955 new cases of tuberculosis reported to the department of health in 1925, which, added to those already known, made a total of 27,172 in the city The registration rate in the city is now 562 per hundred thousand of population, ranging from 698 in Manhattan to 134 in Richmond

Society News—Dr. Michael Schuman has been elected president of the Riverside Medical Society, and Dr. Samuel Morse, secretary, Dr George D Stewart, who was guest of honor at the last bimonthly scientific meeting and dinner at the Hotel Majestic, delivered an address on "An Eye Witness in the Evolution of Surgery"——Dr Bernard Sachs addressed the stated meeting of the New York Academy of Medicine, May 6, on "The Mental and Moral Training of the Normal Child'——The Medical Society of the County of Queens and the Medical Association of the Greater City of New York jointly will visit, June 2, the Carnegie Institute of Washington, Department of Genetics, Cold Spring Harbor, Long Island, and, at the same time, the New York State Fish Hatcheries, and then will dine at Ward's Rest Inn at Center Port.——The Brooklyn Chamber of Commerce and the Medical Society of the County of Kings have approved the formation of a Brooklyn Health Council to coordinate all health agencies, to emphasize preventive medical work and properly to evaluate proposed medical agencies; at the organization meeting of the council, April 28, Mr. Matthew S. Sloan, president of the Brooklyn Edison Company, was elected president, and Dr. John E. Jennings, vice president.——Dr. Edward P. Kolb, superintendent, Suffolk County Tuberculosis Sanatorium, Holtsville, recently delivered a series of three lectures on tuberculosis before the Queens County Medical Society.

OHIO

Health at Cincinnati.—Telegraphic reports to the department of commerce from sixty-eight cities with a total population of about 29,000,000, for the week ending April 10, shows that the highest mortality rate (26.1) appeared for Cincinnati, and that the mortality rate for the group was 17.4. The mortality rate for Cincinnati for the corresponding week last year was 15, and for the group of cities as a whole, 14. There were twenty-four deaths from influenza in Cincinnati during the week of April 10.

Hospital for Wooster College.—An anonymous donor has given $75,000 to Wooster College, Wooster, for the construction of a three story hospital building on the campus, to provide hospital facilities for students who are ill, and to supervise better the general health of the student body. The hospital will be built on Beall Avenue and will be completed by June, 1927. A full-time physician and two nurses will be employed, and funds for the maintenance of the hospital have been provided.

Personal.—Dr. Mont R. Reid, Cincinnati, now temporarily on duty in Peking, China, has been selected to accompany y Chapman Andrews on an Asiatic expedition this sum- .——Dr. Louis H. Senteff has been appointed superin-dent of Mount Logan Sanatorium, Chillicothe, succeeding . James J. Chandler, resigned.——Col. Louis T. Hess, C., U. S. Army, addressed the reserve medical officers a luncheon at the Business Men's Club, Cincinnati, on Mobilization of Reserve Medical Corps for War.” Colonel Hess also visited various hospitals and the Medical College of the University of Cincinnati, and Fort Thomas, Ky., which is on the heights just across the river from Cincinnati.——Dr. Squire S. Beverly has been appointed health commissioner of the city of Toledo, to succeed Dr. Daniel W. Iford.——William H. Dittoe, a sanitary engineer for many years with the state department of health, has resigned to become chief engineer of the Mahoning Valley Sanitary District.——Dr. Horatio Z. Silver, Eaton, has been appointed county physician.——A jubilee was recently held in Cleveland in honor of Dr. Frank E. Bunts, who has been connected with Charity Hospital for about forty years.——Dr. Hermann M. Gunn, Philadelphia, has joined the staff of the New London clinic and hospital.

PENNSYLVANIA

Safety Conference.—The Pennsylvania department of labor and industry of the Commonwealth of Pennsylvania will hold a state-wide safety conference in the House of Representatives at Harrisburg May 28. The program, which has been arranged to stimulate discussion, announces that 247 persons were killed in Pennsylvania in 1925 on construction; 85 by cranes; 99 with electricity; 95 by falling objects and 58 in handling objects, and that 538 eyes were lost. There are 3,400 establishments in the state without any safety organization.

Governor Smith to Speak on State Hospitals.—Governor Alfred E. Smith of New York will address a mass meeting in Philadelphia at the Academy of Music, Monday evening, May 24, under the auspices of the Public Charities Association of Pennsylvania and the Pennsylvania Mental Hygiene Committee. The meeting will be in the interest of a $50,000,000 bond issue for a ten year building program for state hospitals for the insane, feebleminded and for correctional institutions. Governor Smith will give an account of work done in New York to improve the state hospitals. Senator Reed of Pittsburgh will preside at the meeting; the other speaker will be Dr. Horace P. Pike, director, clinical psychiatry, Danville State Hospital.

Society News.—Dr. Walter Timme, clinical professor of neurology, Columbia University College of Physicians and Surgeons, New York, delivered the Emmerling Memorial Lecture before the Pittsburgh Academy of Medicine, April 29, on “The Nature, Character and Treatment of Pituitary Migraine.”——Dr. Arthur C. Morgan, Philadelphia, addressed the Harrisburg Academy of Medicine, April 30, on “The Treatment of Acute Cardiac Tragedies.”——Dr. James J. Walsh, New York, gave the annual Campbell lecture of the Fayette County Medical Society, Uniontown, April 20, on “Funny Things That Have Cured People,” which is said to be a denunciation of medical quackery. The annual Campbell lecture of the Fayette County Medical Society was established in honor of Dr. Hugh Campbell, the first graduate physician to practice medicine in the county.——Dr. John D. McLean, Philadelphia, addressed the ninth annual Child Helping Conference for Schuylkill County, Pottsville, April 20, on “Hearts Damaged in Childhood.”

Philadelphia

Hospital News.—The president, managers and contributors to the Pennsylvania Hospital in West Philadelphia have issued invitations for May 26 to a celebration of the one hundred and seventy-fifth anniversary of the foundation of the hospital.

Endowment Subscribed.—May 1 marked the close of the first year of the fifteen year drive of the University of Pennsylvania for an endowment fund of $45,650,000, with the result that the subscriptions amounted to $7,500,000; subscriptions were received during the year from 10,868 persons, of whom 10,467 were former graduates or students.

Personal.—Dr. Samuel A. Lowenberg has been appointed visiting physician to the Philadelphia General Hospital and to the Northern Liberties Hospital.——Elmer V. McCollum, Ph.D., of Johns Hopkins University, Baltimore, addressed the Philadelphia Home Economics Association at Conwell Hall, April 15, on “Dietary Reforms.”——Dr. John Norman Henry has been nominated for a trusteeship in the University of Pennsylvania.

WEST VIRGINIA

State Medical Meeting.—The fifty-ninth annual meeting of the West Virginia State Medical Association will be at Morgantown, May 25-27; the association will be guests of the Monongalia County Medical Society. The council and the house of delegates will hold preliminary meetings, Monday, May 24, at the Hotel Morgan; the meetings of the association will be at the Elks Club. There will be a conference of secretaries of component societies, Tuesday noon, to discuss organization activities.

CUBA

Society for Study of Mental Diseases.—The Society of Psychiatry and Neurology of Havana, which was recently organized, has held its first meeting; other meetings will be held monthly. Dr. Armando de Cordoba was elected president of the society and Dr. Aristides Mestre, director of publications.

Milk Dispensary for Children.—Under the auspices of the Red Cross and financed by El Club Femenino de Cuba, a milk dispensary has been opened in Havana, which has about thirty children under its care. A pediatrician makes a complete physical examination of each patient and then prescribes a diet, which with the medical treatment is given to the children free. The mothers are trained in hygiene and other subjects related to health. It is the hope of the health authorities that, through the work done in this dispensary, other localities will establish similar institutions.

GENERAL

Award of Priestley Medal.—The American Chemical Society will award the second Priestley Medal to Dr. Edgar F. Smith, emeritus professor of chemistry, University of Pennsylvania, at the Philadelphia meeting of the society in the fall. The medal is bestowed every three years. The first Priestley medalist of chemistry was Ira Remsen, former president and professor of chemistry, Johns Hopkins University, Baltimore.

Found at Dallas.—Dr. Samuel Iglauer, Pearl Market Bank Building, Cincinnati, writes that he found a pair of glasses, with gray frame, in a gray, soft leather case, and that he is holding them for the owner.——A leather key holder containing six flat kays may be obtained from Association Headquarters, 535 North Dearborn Street, Chicago. Refer inquiries to “Lost and Found.”

American Board of Ophthalmic Examinations.—The next examination of the American Board of Ophthalmic Examinations will be held in Denver, September 13, just before the meeting of the Academy of Ophthalmology and Otolaryngology, which convenes in Colorado Springs, September 14. Further information can be obtained from the secretary of the board, Dr. William H. Wilder, 122 South Michigan Avenue, Chicago.

Fellowships in Neuropsychiatry.—The Graduate School of Medicine of the University of Pennsylvania, in cooperation with the Commonwealth Fund of New York, offers four fellowships in neuropsychiatry with especial reference to child guidance. These fellowships, which are at a stipend of from $2,000 to $2,600 per annum, begin, Oct. 11, 1926, and continue for a period of three years. Applications should be addressed immediately to Dr. George H. Meeker, Dean, Graduate School of Medicine, University of Pennsylvania, Philadelphia.

Annual Conference of Health Officers.—The annual conference of state and territorial health officers with the U. S. Public Health Service will be held in Washington, May 24-25. Representatives are expected from every state and territory. Among the subjects to be considered will be the status of sickness and morbidity reports and registration; the merits of a certification system in the sanitary control of shell-fish; the status of smallpox in the United States, and measures for its control. The conference will also discuss the distribution of ethyl gasoline, vaccination of dogs against rabies, and other phases of public health work.

Society News.—The fifth regular session of the International Association for the Promotion of Child Welfare will be held in Rome, May 25-29.——The annual meeting of the American Psychiatric Association will be held in New York, June 8-11, at the Waldorf-Astoria Hotel; final arrangements have been made for the entertainment of the visiting physicians and their wives and guests of the association.——At the annual meeting of the Association of American Physicians, Atlantic City, May 4-5, Dr. Charles F. Hoover, Cleveland, was elected president; Dr. Alfred S. Warthin, Ann Arbor, Mich., vice president; Dr. Francis W. Peabody, Boston, secretary, and Dr. Joseph A. Capps, Chicago, treasurer.

International Organization for Standardization.—The American Engineering Standards Committee called a conference in New York in April at which the national standardizing bodies in eighteen countries were officially represented. The conference drew up a proposed constitution for a new organization to be called the "International Standardization Association," whose object will be to arrange for international agreement on standardization by providing simple systematic means of interchanging information on standardization work; to develop general principles for the assistance of the national standardizing bodies, and to promote uniformity among the standards of the various national bodies. Members of the association are to be the central national standardizing bodies in the countries that accept this constitution. The executive body will be the "plenary assembly," composed of delegates of all the national standardizing bodies; an administrative council will control the finances and administrative matters but will have only advisory powers on important questions. Thus the basis of an international organization for industrial standardization has been made. The location of the seat of the new organization will be determined by the first plenary assembly. The conference recommended that the offices be established in London.

Supreme Court to Decide Pint in Ten Days Limit.—The right of the federal government to limit the quantity of alcoholic liquor a physician may prescribe within a given period is to be decided soon by the U. S. supreme court. The case, which was argued before the court, April 30, originated in a suit filed in 1922 in the U. S. district court of the southern district of New York by Dr. Samuel W. Lambert, with the approval of the Association for the Protection of Constitutional Rights, of which he was then president. Dr. Lambert sought an injunction to restrain the commissioner of internal revenue from enforcing those provisions of the National Prohibition Act limiting the quantity of liquor a physician may prescribe for one patient within a ten-day period. The district court granted the injunction. On appeal by the government, the circuit court of appeals for the second circuit reversed the lower court. Thereupon Dr. Lambert appealed to the U. S. supreme court. Because of the importance of the case, the American Medical Association and the general counsel for the Anti-Saloon League were allowed to file briefs as amici curiae. The closeness of the question is shown by the fact that the district court for the northern district of Ohio and the circuit court of appeals for the second circuit have decided in favor of the government, while the district court for the district of Montana and the district court for the southern district of New York have held that the limitations imposed by Congress exceed its power under the eighteen amendment.

Appointment of Fellows in Medicine.—The Medical Fellowship Board of the National Research Council appointed the following fellows in medicine, April 24:

Name	Field	Location
Dr. Harold A. Abramson, Libman Fellow, University of London	Physiology or medicine	A. V. Hill, London
Dr. Martin H. Dawson, University Clinic, Royal Victoria Hospital, Montreal	Medicine..........	Rufus Cole or F. W. Peabody, Harvard University
Dr. Arthur R. Elvidge, Cooper research scholar, McGill University	Physiology.........	Erlanger, Wiggers or Carlson
Dr. Peter Heinbecker, house surgeon, Presbyterian Hospital, New York	Physiology, surgery.	Gesell or Erlanger
Dr. Francis Heyroth, Seeley Fellow, University of Cincinnati	Biochemistry.......	E. J. Cohn, Harvard University
Dr. Charles G. Johnston, student assistant in surgery, Washington University	Biochemistry.......	H. B. Lewis, Michigan, or D. W. Wilson, Pa.
Dr. Florence M. Macdonald, assistant in pathology, Johns Hopkins University	Neuropathology, neuro-anatomy	Huber, Michigan, or Herrick, Chicago
Dr. Jacob Markowitz, demonstrator in physiology, Toronto	Physiology........	E. K. Marshall, or Erlanger and Gasser
Dr. Walter S. McClellan, resident physician, Bellevue Hospital, New York	Physiology........	Lusk, Cornell
Dr. Hobart A. Reimann, assistant resident physician, Rockefeller Institute, New York	Pathology.........	Anton Ghon, Prague
Dr. Ralph G. Smith, intern, Toronto General Hospital	Pharmacology......	Sollmann or Gasser
Dr. Maurice L. Tainter, instructor in pharmacology, Stanford University	Pharmacology	
Dr. Willard O. Thompson, research fellow in medicine, Harvard University	Biochemistry.......	L. J. Henderson, Harvard Univ.
Dr. Thomas E. Wood, instructor in medicine, University of Virginia	Physiology.........	Sir Thomas Lewis, London
Howard J. Shaughnessy, Ph.D., instructor in public health, Yale University	Bacteriology.......	Jordan, Chicago
William L. Straus, Ph.D., student at Johns Hopkins University	Anatomy	

CANADA

Personal.—Prof. C. L. Starr, University of Toronto Medical School, recently returned from Harvard University Medical School, Boston, where he assumed the chair of surgery for four weeks during the absence of Professor Cushing in Europe.——Dean Primrose, University of Toronto Medical School, has been awarded an honorary LL.D. by the University of Edinburgh.

Hospital News.—The Soldier's Memorial Hospital at Tillsonburg, Ont., which was made possible by the bequest of the late John Smith, was opened, March 22, by the minister of agriculture of Ontario in the presence of an audience which more than filled the building.——An addition to St. Joseph's Hospital, Winnipeg, will be started shortly, and, when completed, will make the total capacity 200 beds.

Society News.—The Canadian Society for the Study of Diseases of Children will hold its annual meeting at Gananoque, Ont., June 11-12, and all scientific meetings will be open to visitors. Further information may be obtained from the secretary-treasurer, Dr. Henry P. Wright, 40 Trafalgar Avenue, Montreal.——The fifteenth annual meeting of the Canadian Public Health Association, the twelfth annual meeting of the Ontario Health Officers' Association and the sixth annual meeting of the Canadian Social Hygiene Council were held at the University of Toronto, Toronto, May 5-7. There was a program of antenatal clinics, child hygiene clinics, nutrition clinics, demonstrations of public health nursing and milk and food control, and visits to the sewage disposal plants, the Connaught laboratories and other places; in addition to prominent Canadian health officials, George E. Vincent, president, Rockefeller Foundation; Dr. Haven Emerson, professor of public health administration, Columbia University, and Prof. Charles Edward A. Winslow, president, American Public Health Association, and professor of public health, Yale University, New Haven, Conn., addressed the convention.——At the twenty-eighth annual meeting of the

Vancouver Medical Association April 29, Archibald W. Hunter was elected president; Dr. Austin B. Schinbein, vice president; Dr. F. W. Brydone-Jack, secretary, and Dr. Walter S. Turnbull, treasurer.——Dr. Hibbert W. Hill, director, Vancouver General Hospital Laboratories, and professor and head of the department of bacteriology, University of British Columbia, addressed the Oregon State Health Officers' Convention, March 31, and the Oregon State Medical Association, April 1, at Portland, on "The Nonrelation of Malnutrition to Infection."

LATIN AMERICA

Training of Specialists in Hygiene in Uruguay.—The *Anales de la Facultad de Medicina*, Montevideo, gives the text of the recent law founding the Instituto de Higiene Experimental and providing for training of specialists in hygiene. The institute is to have four departments, bacteriology, parasitology, serums and vaccines, and the director is to be appointed by the medical faculty of the university, to serve five years.

Oil Company Opens Hospital.—The Venezuela Gulf Oil Company dedicated a new hospital at Bella-Vista, February 27. The hospital has a capacity of thirty beds and is completely equipped to meet the requirements of the company in this region. It will receive, however, employees of other oil companies and private patients also. The present staff comprises, among various other assistants, three American physicians and three American nurses. Dr. L. G. Chacin Itriago, chief of the National Health Service of Venezuela, was the principal speaker at the ceremonies.

Personal.—There are two physicians in the cabinet of Ecuador, namely, Dr. Isidro Ayora, professor of midwifery in the University of Quito, and Dr. A. Hidalgo Nevares, professor of physiology in the University of Guayaquil, who are respectively minister of public welfare and of public instruction.——Dr. G. Aráoz Alfaro has been made an officer of the French Légion d'honneur.——Dr. R. Finocchietto, Buenos Aires, has been delegated to study rehabilitation centers in other countries, as it is planned to open three at Buenos Aires to aid the crippled to become self-supporting.

FOREIGN

Vaccination Against Tuberculosis at Vienna.—The *Wiener klinische Wochenschrift* states that wholesale vaccination of school children against tuberculosis has been undertaken at Vienna. There have been no mishaps so far, but the reports have not yet been received from all the schools.

Graduate Course on Cancer.—Professor Gunsett writes to announce a course of laboratory and clinical study of cancer at Strasbourg, Oct. 8 to Nov. 6, 1926. Ten members of the faculty and visiting specialists will lecture, and Senator P. Strauss, former chief of the public health service, will preside. Dr. Gunsett is director of the regional cancer research center. The detailed program will be sent on request.

Prize for Research in Obstetrics.—The British Medical Association has received a gift of £1,000 from Dr. Katherine Harman, wife of the treasurer of the association, to establish a prize for research in problems incidental to child-bearing. Dr. Harman suggests that the prize be offered once in two years for the best work on any subject chosen by the council which comes within the definition of "disorders incident to maternity," or secondly, in recognition of important work already done on researches instituted that promise good results.

Personal.—The Ramaer medal, awarded for work that during the last five years has contributed most to the progress of neurology and psychiatry in the Netherlands, is to be conferred on Dr. A. de Kleijn, Utrecht, for his pioneer research on the physiology of the otolith apparatus, the static sense, tonic reflexes, etc.——Dr. J. Mijnlieff, Amsterdam, Keizergracht 134, is the secretary for the third International Congress on Rescue Work and First Aid, which meets at Amsterdam, Sept. 7-11, 1926.——Prof. W. Körte presided at the recent fiftieth anniversary celebration of the German Surgical Society; the city of Berlin presented 10,000 marks to the Körte foundation and a souvenir plaque.——The *Deutsche medizinische Wochenschrift* states that Dr. Fischer of the Pathology Institute at Copenhagen has been called to the Kaiser Wilhelm Institut fur experimentelle Therapie, Berlin, for a term of three years as a "scientific guest."——The *Presse médicale* mentions that Prof. F. de Lapersonne, Paris, has received a parchment address from the Mexican Ophthalmologic Society expressing gratitude for the devoted care lavished on Prof. R. Silva during the latter's long, grave illness in France last year.

Foreign Letters

LONDON

(From Our Regular Correspondent)

April 24, 1926.

Physician's Action Against a Hospital for Roentgen-Ray Injury

An unusual action has been heard at the eastern districts local division in the supreme court of South Africa. Dr. Bryne sued for $40,000 damages for a roentgen-ray burn of the left hand, which had left him to a large extent incapacitated for work. It was alleged that this injury was due to the neglect of the East London hospital board to provide proper apparatus with adequate safeguards, or in consequence of Dr. Hollis, then resident medical officer, who was in charge of that apparatus, not being an expert in roentgen-ray work. The injury was incurred during the course of an operation which the plaintiff was performing for the removal of a needle from the hand of a woman (who also sustained a burn). The defendants denied both that the apparatus was defective and that Dr. Hollis was inexpert in its use, and it maintained generally that, even if he were, the board was not legally responsible for his defects. The plaintiff could see the foreign body, but could not remove it. The body broke into three portions and he extracted only two pieces. When Dr. Hollis found that the plaintiff was failing to find the third portion of the needle, he asked to be allowed to attempt it, which he did. The operation lasted an hour and a half, and seven or eight exposures were given, using 10 milliamperes of current. A week later it was discovered that the plaintiff, the patient and the nurse, all of whom had been under the roentgen rays during the operation, had been seriously burned. The plaintiff relied on the breach of duty of the defendant board in failing to employ a person expert in the use of the roentgen-ray apparatus provided by the board. The defendant board admitted the duty to provide a resident medical officer, who, after due inquiry, might reasonably be deemed to be competent to manage such apparatus, and said that Dr. Hollis after due inquiry was reasonably deemed to be competent. It did not admit that Dr. Hollis was as a fact incompetent or that the plaintiff's injuries were due to inexpertness. The board denied that it was aware of any knowledge of inexpertness of Dr. Hollis, or that it was negligent in any way in appointing or employing him, and that even if Dr. Hollis was negligent or inexpert, and the board was negligent in employing him, the plaintiff was contributorily negligent and could not recover damages because: (*a*) the plaintiff, with full knowledge of the apparatus and of its effects, knowingly overexposed himself to the rays for an unduly long period; (*b*) he permitted Dr. Hollis to leave his duties as roentgen-ray operator and to act as the anesthetist, and for a prolonged period to explore for the portion of the needle; (*c*) he aggravated his injury by using his injured hand too soon after the burn and by employing unsuitable treatment. Sir T. Graham, the presiding judge, said that he was not satisfied that Dr. Hollis was a highly skilled radiologist, but he was convinced that at this date the defendant board had every reason to suppose that it had procured in him a competent and zealous radiologist. This being so, whatever action the plaintiff may have against Dr. Hollis, he must fail in his action against the defendant board. He gave judgment for the defendant with costs. Mr. Justice Pittman delivered a lengthy judgment concurring in the finding for defendant with costs, but basing his finding on his opinion that Dr. Hollis was competent at the time material, which, of course, removed from consideration the question as to whether the defendant board was negligent in engaging and employing him.

Statistics of Crime

The statistics of crime for England and Wales for 1924, just issued, contain much of medical interest. The figures of persons tried for indictable offenses are considered to be the best index to the annual fluctuations of crime. The number of persons tried for indictable offenses in 1924 was 57,374. In 1913, the last complete year before the outbreak of war, the number was 63,269, and the quinquennial averages for the preceding twenty years were successively 53,174, 53,833, 60,065 and 66,301. Measured by these figures, crime was increasing before the war, was less after peace, and now does not yet show a tendency to increase or decrease. With regard to murder, for the last fifty years, during which the population has increased from 24 millions to 39 millions, the number of murders in each year has remained almost stationary at about 150 cases per annum, of which for many years past about fifty have been murders of infants aged 1 year and under. In each of the last two years, 1923 and 1924, the total number of murders has been exactly 150, which is equivalent to 3.9 per million of the population. In 1924, fourteen persons were sentenced to death for murder, and in the cases of ten persons the sentences were executed. The figures of murders committed in England and Wales are not comparable with the figures for foreign countries because of differences in the definitions of murder. If, however, the total number of all homicides in certain countries is taken, approximately accurate comparisons can be made. In 1924 the number of homicides in England and Wales (including murder, manslaughter and infanticide) was 274, and the annual average for the five years from 1920 to 1924 was 268. The estimated total population of England and Wales in 1924 was 38,746,020. In the United States, in the registration area inhabited by 93,000,000 people out of the total of 110,000,000 population of the whole continental area of the United States, there were 7,788 homicides in 1922, of which 5,714 were committed with firearms. In Germany in 1921 there were 167 persons sentenced to death for murder; in Italy in 1918, with a population of 36,557,615, there were 1,983 homicides (including attempts) actually denounced to the courts (in England and Wales the corresponding figures for 1918 for such crimes known to the police were 267); and in France in 1913 there were 855 persons tried for homicide. In recent years there has been a slight increase in the figures of sexual crimes in England and Wales. The annual average of the total of this group during the five years 1919 to 1923 was 2,937; the actual total for 1923 was 3,030, and for 1924 it was 3,160. The increase was mainly in indecent assaults on young persons under 16.

Severe Sentence on a Physician for Supplying Morphine Contrary to Regulations

In a previous letter, a case was reported in which a physician was fined for supplying morphine contrary to regulations. In the following case the sentence was much more severe. A physician was summoned under the dangerous drugs act of 1920 for failing on three occasions to enter in a register kept for the sole purpose a certain quantity—50 grains—of morphine purchased by him. There was also a fourth summons for failing in a prescription for morphine to specify the address of the person for whom the prescription was given. He was seen by an inspector with reference to a woman, a drug addict, who had been convicted of forging a prescription. He was found to have been sending her morphine to Glasgow from London. He was informed that she was being treated by another physician, and said he would discontinue treating her. In December, 1925, the woman was again interviewed in Glasgow by a representative of the home office, and from information received, the inspector again went to see the physician. He told him he wanted to inspect his register. The physician said he did not keep a register, and he did not keep any stock of drugs or do any dispensing. If patients wanted any morphine he prescribed for them. That was not true. A day book showed that between January and December, 1925, the physician had prescribed 575 grains of morphine on thirteen occasions, and had seen the woman only six times. The pharmacist's register showed only the prescription made out in the name of the woman, but there were a number of "orders" signed by the physician and headed "For surgery use only," amounting in all to 850 grains. The magistrate said he would like to know whether the persons to whom the physician was alleged to have supplied morphine were drug addicts, or if they had come to any disaster as a result, and was informed that as far as one person was concerned this was so. It was stated by the police that the physician was a specialist in drug cases, and a large number of addicts known to the police were treated by him. The magistrate said that it was necessary in the interests of the public that, when a physician broke the rules and regulations as to the supply of dangerous drugs, he should be severely dealt with. He would sentence the defendant to two months' imprisonment in the second division on each of the first three summonses, and fine him $250 also on each of the three summonses, and a further $250 on the fourth summons, making in all six months' imprisonment and $1,000 fines. Notice of appeal was given.

A Surgeon's Hand

At a meeting of the Liverpool Medical Institution a remarkable and probably unique ceremony took place—the presentation to the institution of a bronze cast of the right hand of the surgeon F. T. Paul. In making the presentation, Mr. Frank Jeans said that the name of Paul was known to every surgeon in the civilized world and would be known 200 years hence—not only because he invented "Paul's tube" but also because he was responsible for much of the progress of surgery made in the past. This hand had been done in bronze from a plaster cast by H. Tyson Smith, the sculptor. It was a remarkable hand, the hand of a man who had worked. It was very like the hand of a cellist or a violinist because it was short and broad. The President called on Mr. Paul, who was present. He had been fond of using his hands from his earliest years, he said, as such use is the only way of training them in delicacy; at the same time, it must be remembered that a gentle touch came from the heart rather than from the hands—a touch inspired by a true sympathy with the patient's tissue.

The Cancer Problem and the Progress of Radium Therapy

Prof. C. Regaud recently gave before the Institut des hautes études in Brussels a series of lectures in which he gave a comprehensive account of radium therapy. The statement that dosage may be computed as the product of the intensity of the application and the time during which it is applied is not entirely accurate. A considerable quantity of radium, if allowed to remain for a few hours within the testis of a sheep, may produce an area of necrosis but only partial sterilization. On the other hand, a much smaller quantity of radium left for a sufficiently long period may produce complete sterilization without necrosis. The time element is of paramount importance. This must be taken account of in clinical therapeutics. The sensibility of tumors to ray therapy, unfortunately, diminishes with successive doses. An endeavor should be made to develop artificial radium sensibility; for example, through diathermy or through introduction into the tumor of substances of high atomic weight in the form of minute particles. There is a great future for the collaboration of chemotherapy and ray therapy. The author hopes for more general use of selective ray therapy in place of caustic ray therapy. All cutaneous epitheliomas yield solely to ray therapy and should no longer be operated on. In new cases, a cure can practically always be effected. Permanent cures are obtained in 50 per cent of cancers of the tongue, and 25 per cent of cancers of the buccal floor. Cancer of the pharynx gives 35 per cent of cures when ray therapy is applied. In cancer of the larynx, the prognosis is less favorable, because the cartilages, rich in lime salts, cause harmful secondary irradiation. Escat's plan of resecting the cartilages before undertaking irradiation looks as if it ought to give good results. Cancer of the esophagus does not give good results, owing to the thinness of the walls and the position of the mediastinum. In cancer of the cervix uteri, surgery and radium therapy are equally promising in favorable cases; but it looks as if the knife would be entirely replaced by radium before long. In inoperable cases, radium properly used gives from 15 to 25 per cent of cures extending over periods of five years or more. Although cancer of the breast is very sensitive to rays, the results are mediocre, because it proliferates early. In cancer of the digestive tract, with the exception of the rectum, progress is minimal, though noteworthy results may be hoped for.

Vaccination Against Smallpox

Addressing the Société médico-chirurgicale of Brabant recently, Dr. Lust proposed a resolution to be sent to the minister of public health demanding that the lower house should pass a law making vaccination and revaccination obligatory. Two neighboring countries, England and the German cantons of Switzerland, have experienced an extensive epidemic of smallpox as the result of the abolition of compulsory vaccination. A certificate of vaccination should be required of every foreigner wishing to reside in Belgium.

Surgical Treatment of Vertigo

Dr. Hautant emphasized recently the good results secured from surgical intervention in certain cases of vertigo; more particularly, neuralgia of the vestibule, an affection occurring in persons around 50 years of age, accompanied often by progressive loss of hearing. The intervention consists of a trephining operation on the labyrinth, its extent varying with the degree of conservation of the hearing. The operative results are excellent; mortality nil; no postoperative suppuration, and no involvement of the facial nerve. The feeling of dizziness disappears, and almost always the hearing improves.

Noncancerigenic Tar

Before the Société belge de biologie, Maisin, Rome and Jacquemin announced that they have discovered that tar produced in the Fisher rotary ovens at a low temperature (from 450 to 500 C.) is not cancerigenic. Various components of this tar (rosin, heavy oils and light oils) were also found to be noncancerigenic.

Medical Examination and License to Wed

In an address before the Société belge d'hygiène, Professor Brachet expressed himself in favor of medical examination of candidates to wed. He does not, however, deny that there are difficulties to be overcome before compulsory examination can become a reality. He pointed out the abyss that separates genetics, or the science of animal and vegetable crossings, from eugenics, the science of human crossings.

Every person living is the result of a multitude of crossings. There does not exist in man any such thing as pure lineage, which is in experimental genetics the first and fundamental condition demanded. The object of eugenics is to develop in the offspring the most useful qualities that man can possess. Many marriages take place which, from the eugenic standpoint, ought never to be consummated; for example, between members of two families that betray marked like defects, though they may give evidence of possessing at the same time very desirable talents, which might result in the birth of a genius. The question, therefore, arises, Is it better for the state to put obstacles in the way of the consummation of a union from which a genius might be born or to run the risk of expending thousands of dollars for the hospitalization of the defective offspring of defective parents?

The trend of the arguments places the whole question on this basis: It does not seem advisable to prevent unsuitable marriages by law, but it would seem well to launch an intensive publicity campaign in which sound logic and good example are the rallying notes. It might be feasible to establish a free service where candidates for marriage could receive prenuptial medical advice, as has been recommended by M. Govaerts.

GENEVA

(From Our Regular Correspondent)

April 20, 1926.

Title of Specialist

Following a recent decision, the title of specialist cannot be used in Hungary until a physician has devoted himself to special study for a given length of time. Physicians who illegally call themselves specialists are subject to a fine. In Germany also the diet has decided that the title of specialist can be granted only by a commission of seven members designated by the council of the medical chamber.

Death of Dr. Maygries

Widespread regret has followed the announcement of the death of Dr. Maygries, agrégé professor of the Paris Faculty and obstetrician to the hospitals of Paris. Overtaken by poverty-stricken old age, this eminent practitioner sought refuge in an establishment of the public charities, where he died. He had delivered 10,000 French children during his long career.

Imagination in Therapeutics

Dr. Gustave Monod of Vichy recently delivered a lecture to the Medical Society of Geneva, entitled "Imagination in Therapeutics; Cagliostro to Coué." Cagliostro, Gruty and Coué, by different methods, having an identical mechanism, effected cures of psychasthenics. These three healers obtained success in foreign lands, never in their own; Cagliostro and Gruty in France, Coué in England and the United States. In Italy, Coué was a complete failure. The medical profession should never despise a therapeutic procedure. Coué has shown that an estimate of the suggestibility of every patient should be made. One patient needs authority, another needs persuasion, and all need sympathy. We are not to imitate the procedures of Coué and other healers, but their effectiveness resides in the fact that they are always themselves. In the development of our personalities, Monod sees the possibility of becoming the best of healers.

International Medical Union

The Central Committee of the Federation of Swiss Physicians has ratified its adhesion to the International Medical Union and will be represented in that body by its president, Dr. Fingerhuth. The union is intended to be a center of information whose permanent agent is to be a general secretary. The council of the union will be composed of two members and a correspondent for each nation belonging to the union. As an example of the work of the union, let us suppose that Finland wants to know how a given medicosocial question has been settled by the medical profession of Switzerland and Italy. Finland's correspondent writes to the general secretary, and the latter transmits his questions to Switzerland and Italy. Copies of the replies are kept by the secretariat, so that little by little its archives will become an international library concerning the practice of medicine.

Importance of Acne

Prof. Charles Du Bois of Geneva has recently called attention to the fact that acne in young persons should be carefully treated because it disfigures adolescents for years and, by leaving cicatrices in adults, may become the starting points of epithelial growths in later life. Prophylaxis requires minute cutaneous hygiene and regular removal of comedones by means of Unna's instrument or pressure with the fingers, care being taken to avoid making any excoriation liable to become infected. Before and after these manipulations, the skin is to be impregnated with a fat dissolving solution, the following being Du Bois' choice: benzine, purified petroleum benzin and xylene, equal parts. This solution causes swelling and irritation of the skin, which is always temporary and without danger.

Arsenic on Apples

On account of the recent legal proceedings in England relating to American apples bearing arsenic, it is likely that a law controlling its use in fruit growing will be submitted to the Swiss federal council for action.

Gastro-Intestinal Hemorrhage of the New-Born

Dr. Salavert records three cases of nurslings who developed melena and hematemesis a few hours after birth. Other methods of treatment have been outclassed by transfusion. Citrated blood, as used by Lewisohn in 1914, was perfected by Helmholz in 1915, the transfusion being made in the superior longitudinal sinus. Statistics show that the hemorrhage was controlled in 96 per cent of the cases, with 89 per cent recoveries, even in the most desperate cases. It is preferable to determine the blood group of the donor and infant, yet no time is to be lost with this examination because several hundred transfusions have shown that the mother's blood can almost always be transfused with impunity.

ITALY

(From Our Regular Correspondent)

March 15, 1926.

The Leonardo Bianchi Foundation

In recognition of the work of Prof. Leonardo Bianchi, senator, as instructor in neurology and psychiatry, a fund has been collected with which to establish at the University of Naples a biennial Bianchi prize, to be awarded to the medical graduate who submits the best work on neuropsychology.

The Crusade Against Malaria

The municipality of Rome and the Rockefeller Foundation will cooperate in creating in Rome an institute for the study of malaria in Italy, and particularly in the Agro Romano. The institute will be housed in the Palazzo della Farnesina, and will comprise a department for biologic study, an exhibit of sanitary engineering, a library with modern literature on malaria, and a propaganda department for the demonstration of various systems and installations employed in the crusade against malaria. The governor of Rome has arranged with lessees and owners of land in the Agro Romano to undertake the permanent elimination of stagnant pools. Reservoirs of water must be rendered harmless, bunkhouses of agricultural laborers must be whitewashed, and mosquitoes and other insects which breed must be destroyed. Proprietors and managers of country estates must report all cases of malaria, whereupon the governor of Rome will provide the needed treatment free of charge.

Italian League for the Prevention of Nervous and Mental Disease

The *Lega italiana per la prevenzione delle malattie nervose e mentali* has been founded in Rome. Its purpose is analogous to that of similar leagues already established in the larger countries of Europe and America. Honorary chairmen are Prof. Leonardo Bianchi, senator, and Professors Morselli and Tanzi, active chairmen are: Professors Ettore Levi, Ferrari and Medea. The following chapters have already been organized and have begun work. Lombardy (Prof. Medea), Piedmont (Prof. Lugaro), Liguria (Prof. Vidoni), Emilia (Prof. Ferrari), Marches (Prof. Modena), and Abruzzi (Prof. Del Greco). At Rome, a Latium chapter has been established which is housed in the Istituto italiano di igiene e previdenza sociale, under the chairmanship of Prof. De Santis of the University of Rome.

The Death of General Lorenzo Bonomo

The death is announced in Bari, his native city, at the age of 69, of Prof. Lorenzo Bonomo, general in the reserves of the army medical corps. Bonomo had held for ten years the chair of war surgery and operative medicine in the Scuola di sanità militare and had been successively director of various hospitals in time of peace. During the war, he was sanitary director of the army medical corps and later of the third army corps, a post which brought him promotion to the rank of general. He was consultant and chairman of the international sanitary commission, instructor in the Università castrense di S. Giorgio di Nogaro, was appointed chief inspector of the Sanità militare italiana, and was the last person to hold that post, it being now abolished. At his request, he was given a position with the reserves, and was then again called into active service in the ministry of finance, being appointed chairman of the Commissione superiore di visite in connection with the administration of war pensions.

Scientific Lectures at the Scuola di Sanità Militare

In the Scuola di sanità militare, a series of lectures on live topics will be given during the current year, by professors of the various Italian universities. Two lectures have already been given.

The Superabundance of Physicians

Italy has rather an overabundance of physicians. During the war and the years immediately following, the annual number of graduates in medicine and surgery was much greater than during the preceding period, so that now, in the urban centers, there are about 800 inhabitants to one physician.

A New Course in Legal Medicine

At the University of Naples a new course in legal medicine dealing with work in prisons has been organized. Professor De Crecchio, director of the Manicomio Giudiziario in Naples, will have charge of the course. In his introductory lecture, Professor De Crecchio emphasized the need of far-reaching reforms in punitive law. The speaker brought out that the old conception of the prison physician's duties was no longer tenable, and that he must now take his part in corrective work. Professor De Crecchio accentuated the importance to the prison medical specialist of traumatology, aphrodisiology and toxicology. He stated that the prison constituted a veritable psychopathologic clinic, rich in material bearing on the administration of justice and the complex personality of the criminal.

Official Consultation Centers on Marriage

In a decree dated February 19, the Prussian minister of public welfare recommended the creation of marriage consultation centers (*Ehebcratungsstellen*). The purpose of these centers will be to determine by medical examination whether the health of applicants justifies marriage. The results of examinations will be recorded in a marriage testimonial (*Heiratszeugnis*). The present decree does not propose to make the medical examination compulsory, nor are there any medical restrictions on marriage or any requirement that certificates of health shall be exchanged between the parties to the contract. The consultation centers will serve to establish suitability for marriage and to give advice on medical matters pertaining to marriage but not on other questions bearing on sexual relations. Professional secrecy is imposed on the examiners. The examination will be conducted according to the rules proposed by Hirsch to the Prussian Health Council. The form for the marriage testimonial was also prepared by Hirsch. It comprises the following four questions: 1. What objections, if any, are there to the marriage of the examinee? 2. What dangers, if any, are presented for the other party to the contract? 3. What dangers, if any, would eventual offspring incur from the marriage? 4. What defects, if any, does the other party to the contract present that appear to constitute an objection to the marriage? Hirsch emphasized the dangers of child bearing for women of inferior constitution, and pointed out the dangers from venereal diseases, especially for women. He explained also the risks that posterity incurred. The marriage testimonial requires also replies to the following two quesions: 1. On the basis of the findings made, are there any serious objections to the applicant entering into the marriage relation? 2. Should the applicant postpone his (or her) marriage, and, if so, for how long? It is left to the discretion of the applicants to take whatever course they choose after the contents of the marriage testimonials become known to them. Hirsch discussed the question of whether the marriage testimonials should be made out by the *"Amtsarzt,"* by a special adviser (which would require the creation of a new office), or by general practitioners. The decree recommends the appointment, as special advisers, of physicians who are mature, experienced and possessed of broad scientific knowledge. Hirsch thinks that the decision as to the suitability of applicants for marriage licenses should be left to general practitioners. He is fully aware that, at present, the average physician does not possess the adequate knowledge for the task, and repeats his former demands that in the university medical course the theories regarding propagation, the physiology, pathology and sociology of marriage, and the clinical problems of heredity be taught in the medical clinics.

The Operation of the New Law Pertaining to the Care of Cripples

During the years from 1920 to 1924, the Prussian welfare leagues, exclusive of Schleswig-Holstein and Nassau, have turned over 18,600 cripples to institutional care. On the basis of the census of 1906, which gave as 29,000 the number of cripples in Prussia in need of homes, nearly two thirds of that number had been provided for, although Prussia's new law pertaining to the care of cripples has been in operation only five years. To be sure, the undernutrition of the war and postwar periods has produced a large number of new cripples. Up to 1925, the provinces of Prussia expended 6,500,000 marks in the application of the law. According to the law, the task of preventing crippling is part of the public welfare work. The Rhine Province has appropriated 100,000 marks for purposes of prophylaxis. This sum is to be used for the creation of orthopedic courses in gymnastics; for combating rickets, and, finally, for the industrial education of cripples. There is still a dearth of trained orthopedic physicians. Until the universities can supply this need, several communities should combine and employ a specially trained physician.

JAPAN

(From Our Regular Correspondent)

April 6, 1926.

The Cause of Rabies

Dr. K. Sukegawa, after seven years of research, has cultivated the micro-organism that causes rabies. He believes that the Negri bodies are not the cause of this disease. In his first trial of infecting rabbits with this virus, fifty-eight days passed before rabies appeared in them and the symptoms of the disease were imperfect. At present, in the twelfth generation, the disease appears in twelve days.

The Imperial Academy Prizes

In the general meeting of the Imperial Academy, the prize winners for the year 1925 were selected. The imperial prize was conferred on a geologist, aged 26. The academy prize was awarded to Prof. Dr. Seizo Fujinuma of the Medical College of Aichi University, whose work was "The Histologic Study of Oxydase." He is said to have pursued his researches for more than ten years, meanwhile making a clinical study of the pathologic changes involved. His published reports amount to twenty-four, of which the last gives authority to the theory of oxidation in the tissue cells. The imperial wedding commemoration prize of the Osaka *Mainichi-Shimbun* (Daily News) was given to Prof. Dr. C. Ogata and Prof. Dr. J. Shimazona of the Medical College of the Tokyo Imperial University, who worked on the same subject, "The Experimental Study of Lack of Vitamin B." Both came to the conclusion that when man and other animals suffer from this disease, the lack of proper nourishment, the loss of weight, the impoverishment of blood, etc., are evident, but in the heart and veins no change such as often found in beriberi is to be seen.

The Insane and Asylums

Dr. Naoki Sugita informs us that Japanese are taken with mental diseases in the spring and summer more than in the other seasons. In the suburbs of Tokyo is a hospital for the insane with 700 beds, while the Osaka prefecture is now building one that will admit 300 patients. There are fourteen additional public and forty-one private asylums in Japan proper, besides many hospitals, public or private, with clinics for mental diseases.

Union Hospital

April 27, a meeting was held in Tokyo to establish a union hospital in the suburbs of Tokyo. The hospital will make it unnecessary for practitioners, able and experienced but without hospitals of their own, to send their patients to bigger hospitals. Also, their patients need not undergo the inconvenience and expense of changing physicians.

Physical Education

The authorities have decided that in the next budget year they will establish a physical culture staff consisting of forty-seven officials of so-nin rank and ninety-seven officials of han-nin rank, who shall be posted in every prefecture throughout Japan. The educational department has also established a research institute of physical education. The main building and fine gymnasium of the institute has just been completed in the suburbs of Tokyo. There is to follow a track 330 meters long, tennis courts and a swimming pool, the whole site and compounds covering about 40,000 square meters and being surrounded with beautiful woods and small valleys. The institute is intended to conduct research on physical education. The institute has much to perform in the future in giving courses of lectures and training, coaching athletes and publishing books.

Increase of Physicians

According to figures published by the department of home affairs of Japan, the number of physicians in this country in 1925 was 43,702, including 1,271 new medical graduates. Although for the last ten years there has been a decrease of 937 practitioners, the number of new graduates increases by about 350 more year by year. Dr. Sakuzo Ujihara in the department of home affairs is of the opinion that the greater the number of practitioners, the higher the medical fees; for each practitioner is apt to distribute the cost of his own maintenance among his patients. The increase of our population being about 700,000 a year, he argues that we must limit the number of new physicians to 500 at most. His private opinion is that the department of home affairs should license only those who pass the government examination. Dr. Nishimine argues that, though the department of education must regulate the number of medical graduates, our country is still in need of more and better practitioners in order to maintain our national health.

Periodicity of Conception

According to Dr. Kochu Narumi of the Kiuchi Institute, the periodicity of conception of 1,000 Japanese women can be classified into five types: (1) two year type (the period between conceptions is quite regular—from a year and a month to two years); (2) three-year type (from two years and a month to three years); (3) four-year type (from three years and a month to four years); (4) five-year type (from four years and a month to five and more than five years); (5) unusual types. The average period of all except those of the unusual types is just two years, three months and eighteen days. In a woman of the standard three-year type, intervals of conception maintain the same periodicity irrespective of her increasing age. The women of two-year and four-year types also repeat their conceptions regularly.

The Central Antituberculosis Society

The twelfth general joint meeting of the local antituberculosis societies in Japan, held at Nagano this month, has decided that a central association shall be organized with the name of the Japan Central Antituberculosis Society in order that it may formally send representatives to the international antituberculosis association, to be held in Los Angeles next autumn. The newly organized society is to consist of all members of every public or private society in Japan which is interested in tuberculosis.

Abolition of "Patent Medicine" Tax

Readjustment of taxation being the main policy of the present Japanese cabinet, Mr. Hamaguchi, minister of finance, proposed that the "patent medicine" tax laws should be abolished. His argument was that such laws imposed a tax on the poor, who would sooner take "patent medicines" than consult physicians. In spite of the strong opposition of the medical profession, the bill for abolition of these taxes passed the last session of the imperial diet.

Marriages

Hanns Bernhard Mueller, Ann Arbor, Mich., to Miss Henny R. Cramer of Lincoln, April 18.

John Vincent Lambert to Miss Margaret May Carroll, both of Chicago, May 1.

Albert L. Schneider, Brady, Neb., to Miss Flora Crane of Denver, recently.

Deaths

Arthur Righton Dray, Beirut, Syria; Medico-Chirurgical College of Philadelphia, 1905; also a dentist; professor of oral surgery, operative dentistry, and director of the school of dentistry, American University of Beirut; formerly a practitioner in Philadelphia; aged 53; was killed, March 4, by an insane servant.

James H. Seyler, Preemption, Ill.; Western Reserve University School of Medicine, Cleveland, 1867; University of Pennsylvania School of Medicine, Philadelphia, 1868; also a druggist; for twenty-five years postmaster; aged 83; died, April 25, of senility.

Charles Louis Chasins ⊕ New York; Cornell University Medical College, New York, 1902; specialized in otology, laryngology and rhinology; on the staff of the Community Hospital; aged 46; died, April 29, of coronary thrombosis.

Thomas Martin Darwin, Cooper, Texas; Medical Department of the Tulane University of Louisiana, New Orleans, 1902; member of the State Medical Association of Texas; served during the World War; aged 47; died, March 30.

Theodore Clement Wood, Haverstraw, N. Y.; Medical Department of the University of the City of New York, 1879; member of the Medical Society of the State of New York; aged 72; died in January, of dilatation of the heart.

Elmer E. Vaughan ⊕ Chicago; Hahnemann Medical College and Hospital, Chicago, 1889; formerly professor of surgery at his alma mater; aged 60; died, April 30, of splenomyelogenous leukemia.

James Dennistoun Jones, Basswood, Manitoba, Canada; M.R.C.S., England, 1914; L.R.C.P., London, 1914; M.B., B.Ch., University of Cambridge, 1918; aged 38; died, January 20, at Dauphin, of heart disease.

John L. Harris, Webster, S. D.; Hahnemann Medical College and Hospital, Chicago, 1875; Medical Department of the University of Illinois, Chicago, 1891; aged 77; died, April 16, of heart disease.

Le Baron Wilmot Jones, Pleasantville, N. Y.; Bellevue Hospital Medical College, New York, 1892; on the staff of the Ossining (N. Y.) Hospital; aged 55; died, April 28, following a long illness.

George T. Hagen, Johnson City, N. Y.; Syracuse University College of Medicine, 1923; served during the World War; aged 26; died, April 4, at the Johnson City General Hospital, of pneumonia.

Henry Clinton Peninger, Lacamp, La.; Memphis Hospital Medical College, 1901; member of the Louisiana State Medical Society; aged 49; died recently, at Glenmora, of chronic interstitial nephritis.

Mars W. Carpenter, Cleveland; Western Reserve University School of Medicine, Cleveland, 1902; member of the Ohio State Medical Association; aged 58; died, February 17, of cerebral hemorrhage.

Alton J. Turney, Crutchfield, Ky.; Vanderbilt University Medical Department, Nashville, Tenn., 1891; member of the Kentucky State Medical Association; aged 57; died, April 13, of heart disease.

Charles N. Powell, Deweyville, Texas; St. Louis College of Physicians and Surgeons, 1893; member of the State Medical Association of Texas; aged 57; died, February 18, of pneumonia.

Henry Wallwin, Barrie, Ont., Canada; University of Toronto Faculty of Medicine, Toronto, 1889; formerly member and chairman of the board of education; aged 66; died, March 1.

Millard F. Stults ⊕ Wiota, Iowa; College of Physicians and Surgeons, Keokuk, 1878; secretary of the Cass County Medical Society; aged 69; died suddenly, April 16, of heart disease.

Ernest Raymond Schilling, Glen Cove, N. Y.; Albany Medical College, 1915; member of the Medical Society of the State of New York; aged 36; died, April 24, of pneumonia.

Harry Coleman Dunlavy, Shelby, Iowa; Northwestern University Medical School, Chicago, 1917; aged 32; died, April 19, at a hospital in Blair, Neb., of injuries received in an accident.

John James Mudd, Hardyville, Ky.; University of Louisville School of Medicine, 1876; Jefferson Medical College of Philadelphia, 1890; aged 80; died, April 12, of senility.

Wilbur G. Melaas ⊕ Beloit, Wis.; Rush Medical College, Chicago, 1905; aged 42; died, April 17, at the Emergency Hospital, of shock and hemorrhage following a cholecystectomy.

Eli Stillman Bailey, Chicago; Hahnemann Medical College and Hospital, Chicago, 1878; aged 74; died, April 26, at the Hinsdale (Ill.) Sanitarium, of cerebral hemorrhage.

William D. Matney, Greenville, Ill. (licensed, Illinois, 1878); Civil War veteran; aged 85; died, April 9, at the Soldiers' and Sailors' Home, Quincy, of paralysis.

Jonathan J. Evans, Friend, Neb.; Eclectic Medical Institute, Cincinnati, 1880; Columbus Medical College, 1883; aged 71; died, April 5, of cerebral hemorrhage.

Marion Thrasher, San Francisco; University of California Medical School, San Francisco, 1890; aged 83; died, April 4, at Palo Alto, Calif., following a long illness.

Maurice Enright, Brooklyn; Medical Department of Columbia College, New York, 1885; aged 53; died, April 8, of bronchopneumonia and chronic endocarditis.

James M. Grant, Petersburg, Ky.; Medical College of Ohio, Cincinnati, 1873; Jefferson Medical College of Philadelphia, 1875; aged 73; died, March 24, of paralysis.

Clarence P. Battles, Hot Springs National Park, Ark.; Rush Medical College, Chicago, 1879; formerly a druggist; aged 72; died, March 31, at Girard, Pa.

Michael Charles Golden, Taunton, Mass.; University of Vermont College of Medicine, Burlington, 1881; aged 71; died, April 13, of cerebral hemorrhage.

John W. Forrest, Lynnville, Ky.; University of Tennessee College of Medicine, Memphis, 1900; aged 72; died, January 14, of chronic nephritis.

Robert Simpson Paxton, College Corner, Ohio; Miami Medical College, Cincinnati, 1882; aged 73; died, April 17, of angina pectoris.

John R. Woltz, Dobson, N. C.; Medical College of Virginia, Richmond, 1867; Civil War veteran; aged 85; died, April 10, of senility.

John W. Coy, Bolivar, Mo.; St. Louis College of Physicians and Surgeons, 1893; aged 56; died, April 6, of bronchopneumonia.

Fred Henry Fearl, Orange, Mass.; University of Vermont College of Medicine, Burlington, 1890; aged 62; died, March 24.

Thomas Henry Morgan ⊕ New York; Trinity Medical College, Toronto, Ont., Canada, 1897; aged 57; died, April 9, of uremia.

Mary M. Huntley, Olympia, Wash.; University of Buffalo Department of Medicine, 1896; aged 64; died, March 3, at Puget.

John Donald Proctor ⊕ Keene, N. H.; Tufts College Medical School, Boston, 1897; aged 57; died, April 8, of pemphigus.

Frederick E. Fooks, Baltimore; Washington University School of Medicine, Baltimore, 1873; aged 77; died, March 25.

Alvin A. Williamson, Marshall, Ind.; Medical College of Indiana, Indianapolis, 1898; died, April 5, of heart disease.

Charles H. Boaz, Mattoon, Ill.; Chicago Homeopathic Medical College, 1890; aged 72; died, April 24, of angina pectoris.

Edward W. Toole ⊕ Selingsgrove, Pa.; College of Physicians and Surgeons, Baltimore, 1881; aged 74; died, March 13.

James Wallace Smuck, Toronto, Ont., Canada; Victoria University Medical Department, Toronto, 1892; died, March 6.

Lewis Cass Landon, Indianapolis (licensed, Indiana, 1897); Civil War veteran; aged 84; died, April 16, of heart disease.

William H. Lewis, Mount Carmel, Pa.; Jefferson Medical College of Philadelphia, 1888; aged 65; died in March.

Miles Cabel McKee, Fox Creek, Ky.; University of Louisville School of Medicine, 1918; aged 43; died, April 20.

Joseph Mayo Harris, Sedalia, Mo.; Meharry Medical College, 1893; aged 67; died, March 29, of heart disease.

Everett Morton Evans ⊕ Mecca, Ind.; Pulte Medical College, Cincinnati, 1895; aged 61; died, February 20.

Antonio Capozzi, New York; University of Naples, Italy, 1886; aged 64; died, April 9, of lobar pneumonia.

Samuel J. Lisman, Oaktown, Ind.; Medical College of Ohio, Cincinnati, 1872; aged 84; died, February 20.

J. C. Hurst, Saxon, W. Va. (licensed, West Virginia, under the Act of 1881); died, March 19.

J. C. Wilhite, Sardis, Tenn. (licensed, Tennessee, 1908); died, April 1, of heart disease.

PROPRIETARY MIXTURES SYNDICATE

Another Medical Fraud Debarred from the Mails

Kansas City, Missouri, which until recently, at least, has had the unenviable distinction of harboring some of the worst medical mail-order frauds in the country, is, or possibly we should say was, the home of the Proprietary Mixtures Syndicate, Inc., and Yonga Yoga Scientist, Inc., two imposingly named *pieces* of quackery operated by one Thomas W. Douglas and his wife Maye. Douglas' scheme was to sell through the mails a number of "patent medicines" which Douglas called "Formulations." His method of diagnosis was to require the birth date and from this he pretended to be able to determine what ailed the victim, and the evidence showed that he usually extracted about $100 from each person that "bit" on his scheme.

On March 13, 1926, Douglas was called on to show cause by April 9 why a fraud order should not be issued against him and his fake concern. He appeared on that date with his attorney, Austin F. Canfield of Washington, D. C. On April 17, 1926, a fraud order was issued against Proprietary Mixtures Syndicate, Inc., Mrs. M. Douglas, Thomas Douglas and Yonga Yoga Scientist, Inc.

The memorandum to the Postmaster General of Judge Horace J. Donnelly, Solicitor of the Post Office Department, gives in detail the government's case against these quacks. We quote in part from the memorandum:

"Mr. Thomas W. Douglas and wife, Maye Douglas, are engaged in the business of selling through the mails certain medicinal preparations called 'Formulations,' which, it is claimed, will cure remitters of practically every disease and ailment known to humanity, including cancer, tuberculosis, Bright's disease, stomach, liver and kidney 'troubles,' genito-urinary ailments, and even blindness in some instances. All the information Douglas and his wife claim is really necessary for treating a prospective patient through the mails is the date of birth."

The memorandum continues:

"The evidence shows that Mrs. Douglas has no medical training whatever, but Mr. Douglas claims he studied certain branches of medicine in this country and abroad, and that he made it a practice to pick herbs of various kinds since he was a boy. He was rather hazy as to the particular studies he pursued in several universities he mentioned. He claimed he paid for his instruction, but admitted he was not enrolled in any medical institution. He admitted that he does not reach his conclusions from a medical standpoint, but makes his alleged diagnoses astrologically or by 'rule.' He testified, however, that he does not need to know the exact moment and place of birth, but claimed that all the information he needs to determine what diseases or ailments individuals are suffering from is to have simply the date of their birth.

"According to the evidence Douglas employs no physician, pharmacist or chemist, all the work being done by himself and wife at their home. Sometimes they have a temporary employee. The medicines are put up in part by Parke, Davis & Company, and Douglas informed the inspector that Charles H. Hunter, then in Africa, doing 'root and herb' work, mixes 'different strengths' of the medicines used. Douglas stated he had quite a stock of medicines on hand already mixed, sufficient to last until Hunter returned. Douglas calls his medicines 'Formulations,' and informed the inspector that he has from 1 to 46,000 'numbers,' representing 'different elements of strength.' At the hearing he was either unable or unwilling to state the cost to him of his several medicines or 'Formulations.' He stated the 'Formulations' were secrets, and that he charged patients from $35.00 up for the diagnosis and treatments. The evidence shows that some persons were induced to pay him sums of several hundred dollars. I find from the evidence that the favorite method being practiced by Douglas on credulous persons is to get them to purchase the regular treatment and then to have them purchase a further supply to keep them from 'going back,' or, as he also says, to keep them from becoming 'stagnated.' Douglas informed the inspector that the claims made for the medicines are based on so-called testimonials from laymen.

"Mr. Douglas was asked at the hearing to state the basis used by him in determining from what diseases or ailments a particular person suffered. He replied that the individual's birthdate enabled him to say which of the signs of the Zodiac the individual came under, whether within the 'division of earth, air, fire or water,' and that by means of certain mathematical calculations which he claims to make he could tell just what disease or ailment the individual had. He admitted he might make occasional mistakes. He alleged that while persons born under the same sign of the Zodiac are 'predisposed' to the same diseases and ailments, yet they don't all have the same trouble, but that he is able, with nothing else at hand concerning the individual except the birthdate, to differentiate between the various ailments in the most minute detail. He admitted that persons born under a certain sign of the Zodiac might have the same disease as persons born under any other sign, but that this also made no difference so far as his ability to diagnose the case is concerned."

"Concerning his method of diagnosing, Mr. Douglas was either unwilling or wholly incapable of explaining it, but claimed he used secret methods. He sought in every way to becloud the issue, regardless of questions asked him in an effort to bring out the facts. He claimed that he and Mrs. Douglas were the only ones who knew the secret.

"I am convinced from the evidence in the case that the claims of Douglas respecting the so-called diagnoses are false and fraudulent.

"Douglas does not advertise in newspapers, or circularize through the mails. He obtains 'patients' by distributing printed cards [see illustration.—Ed.] through the medium of former patients or agents who, he says, travel from place to place selling his medicines on commission."

Douglas assumed the title of "Professor" as the result of some study alleged to have been made by him in India. Both the Proprietary Mixtures Syndicate, Inc., and the Yonga Yoga Scientist, Inc., were incorporated in Arizona. Both of them were owned lock, stock and barrel by Douglas and his wife.

"Mr. Douglas testified at the hearing that since beginning his operations in 1922 he has treated approximately 1,500 persons. He also stated that the charges for the treatment are from $35.00 up. On this basis he would have taken from the public a minimum of $52,500. It is much more probable, however, that these figures would run much higher, as the evidence shows patients are usually asked to pay Mr. Douglas around $100.00."

Judge Donnelly's memorandum closed with the following pertinent statement:

"*According to the medical testimony adduced by the Government* in this case, many of the diseases undertaken for treatment by Douglas are of a very serious nature, and unless properly diagnosed and intelligently treated may result disastrously to the sufferer. Such diseases and ailments often tax to the utmost the knowledge and facilities of the most skilled physicians and surgeons with the patient directly under observation.

"The futility of treatment by mail, where the patient has never come in contact with the physician, to say nothing of a layman attempting to diagnose and treat, is readily apparent. As stated before, Douglas claims to make his diagnosis by 'rule.' He needs no symptoms, just the birthdate. His conclusions, which he admits are the same whether the person is real or imaginary, are thus arrived at by combining the so-called rule or rules with what additional information he may obtain from the patient and possibly an active imagination."

Some late activities of the Proprietary Mixtures Syndicate, Inc., were brought to the attention of the Bureau of Investigation of the American Medical Association some weeks ago. A Colorado physician sent to the Association a number of nostrums put out by this concern with the request that information be furnished as to whether or not any of them contained iodine. It seems that a patient of the doctor had paid $236 for this quackery, which was to cure her of blindness. The woman had thyroid adenoma, and following the use of the nostrums became seriously thyrotoxic. One of the specimens sent in by the doctor was found to be essentially tincture of iodine!

Correspondence

"THE SPLEEN IN MEASLES"

To the Editor:—In The Journal, April 17, in the editorial on "The Spleen in Measles—An Overlooked Symptom," it is stated that "only now has it been made unmistakably clear through the records of Bleyer of the St. Louis Children's Hospital that enlargement of the spleen should be included in the symptomatology of measles." And at the close, "And all of this is the simple finding regarding one of the largest organs in the body in the examination of a few hundred sick children, while half a hundred textbooks have denied, disregarded or debated the symptom."

Since 1923 I have been calling attention to this symptom *in my reports to the International Health Board, to the state* board of health, and in published letters and articles, begging those who had opportunity to follow the matter up. The priority of discovery makes no difference, but the difference in conclusions reached should cause us to peruse the matter further.

In Public Health Bulletin 156, page 133, I am quoted as saying at the New Orleans meeting in 1924: "But as valuable as the method is, it must be remembered that other things (besides malaria) may enlarge the spleen. Dawson, Ga., has been drained and is practically free from malaria. In examining the first three grades of the school there, I found fully 75 per cent of the children with enlarged spleens, though there was no *history of malaria, and they were as pink and* healthy a bunch as I have ever seen. . . . Every one of them had just recovered from measles.

"I visited a number of other towns (Cordele, Vienna, Unadilla) and counties, and I soon got so I could examine a few children and state that there had been an epidemic of measles among the children. And I never once went wrong.

"The enlargement from measles is not great, usually what Dr. Darling calls 'palpable on inspiration,' and has a doughlike or boggy feeling, distinguishing it from the hard, sharp-edged spleen of malaria. The surprising thing about these measles spleens was the length of time that they remained enlarged. After thirty days, 85 per cent were still palpable, with a slow decrease each month until after six months, about 20 per cent were still palpable. . . . Following about twenty cases of enlarged and troublesome tonsils I found an enlargement. This makes me think that even a throat specialist might make use of this method of examination. They are divided as to whether to remove all enlarged tonsils or not. If I had a case of enlarged tonsils with a palpable spleen I would surely remove those tonsils, for I would know that they were poisoning the patient.

"I am dwelling on these things in the hope that others will take it up and see what we can find out about the spleen following scarlet fever, smallpox and other infections"

Your editorial mentions the "almost abrupt appearance of the spleen during the eruptive stage of measles, and the suddenness of its disappearance as the rash subsides." I never saw any cases during the eruptive stage. All my patients had recovered and were back in schools, and the thing that interested me was the fact that many of them were still palpable for six months. I cannot explain this difference, unless it is due to different methods of palpating. In our method the patient lies with head to the examiner's left, flat on back, perfectly relaxed, knees flexed. The examiner's fingers are placed rather lightly at the border of the patient's left ribs, and the patient is requested to breathe deeply. With practice, a very small spleen may be felt to descend and tap the fingers.

In rubella and in chickenpox I have not been able to demonstrate an enlarged spleen, and I am wondering whether every epidemic of measles would present this sequela with equal constancy. Certainly we need others to record their observations.

M A. Fort, M D., Bainbridge, Ga.
Director, Tri-County Health Work

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed Every letter must contain the writer's name and address, but these will be omitted, on request.

HEALING OF DRILL HOLES IN BONE

To the Editor —Please advise me as to the time required, following the drilling of an osteomyelitis, adjacent to the upper epiphyseal end of the tibia but not proximal to it, for such drill holes to heal so thoroughly that they will not show on a roentgenogram, assuming that the drill was of moderate or relatively small size

L. H. Childs, M.D., Flint, Mich.

Answer.—So far as we know, there never has been a statement of observations of this nature in the literature. Healing may take months or even a year, depending on the size of the drill holes, in a case in which the osteomyelitis was minimal.

"IRRITATION FOLLOWING SHAVING CREAMS"

To the Editor.—In The Journal, April 17, appeared a note relative to eczema from the use of "Molle" and "Barbasol." I can add to these reports a case of edema The patient had a dry, scaly skin and I suggested using one of these creams after shaving, instead of soap and water. Within five minutes after use of Molle, the patient's face swelled almost beyond recognition. The condition was relieved by epinephrine administered hypodermically. I wrote to the makers of the product, explaining the case and requesting information as to the ingredients of their cream, as I wished to discover the offending protein I received, however, only a polite but meaningless letter H. F. A., M D.

INJECTION OF TRYPARSAMIDE

To the Editor —I have received a circular which says that tryparsamide may be given subcutaneously. While giving an injection of it into a small vein, I unhappily got a small amount of it into the tissues outside the vein, and an abscess resulted Is it supposed to be a severe irritant or is it safe to give it subcutaneously as stated? Please omit name

M.D , Chicago.

Answer —The general experience of all physicians who have used tryparsamide extensively has been that it is almost free from any local irritative action, and that the patient experiences no discomfort if part of the injection goes outside the vein. Thus, Wade H. Brown and Louise Pearce (The Journal, Jan. 5, 1924, p. 5) write that "very slight local irritation is produced by subcutaneous or intramuscular injections." However, as a matter of fact, the drug is almost exclusively given intravenously.

SCHOOLS OFFERING SUMMER COURSES IN 1926

Prepared by the Council on Medical Education and Hospitals

California

Stanford University School of Medicine, 2398 Sacramento Ave, San Francisco.—Courses are offered for qualified graduates in medicine and undergraduates of this and other schools for clinical and laboratory work in the following departments as special workers: pharmacology, pathology, general medicine, diabetes, electrocardiography and basal metabolism, chest diseases, pediatrics, neuropsychiatry, skin and syphilis, metabolism laboratory, radiology, physiotherapy, general surgery, orthopedic surgery, genito-urinary surgery, ophthalmology, otorhinolaryngology, surgical pathology, obstetrics and gynecology, and female urology. Summer term begins, June 15, and ends, September 1. Dr. William Ophuls, dean.

University of California Medical School, Parnassus and Third avenues, San Francisco.—Courses for qualified graduates in medicine, given in general medicine, pediatrics, gastro-intestinal diseases, dermatology, syphilology, radium therapy, general surgery, orthopedic surgery, otorhinolaryngology, ophthalmology, genito-urinary diseases, general pathology, roentgen ray, obstetrics and gynecology, circulatory diseases, laboratory diagnosis, neurology and neuropsychiatry, and neuro-otology. Summer term begins, June 7, and ends, July 3. Dr. L S Schmitt, acting dean.

Colorado

Colorado School of Tuberculosis, Colorado Springs — Course designed for qualified graduates. Term begins, July 1, and ends, August 1. From August 3 to 10, opportunity will be offered for practical work in the various sanatoriums. The preference of the students for special subjects, such as laboratory methods, roentgen ray, artificial pneumothorax and physical diagnosis, will be consulted as far as possible. Dr. G. Burton Gilbert, secretary.

University of Colorado School of Medicine, Denver.—Courses open for undergraduate or graduate students, in anatomy, bacteriology and public health, biochemistry, pathology, clinical pathology, physiology and pharmacology. Summer session divided into two terms. The first begins, June 21, and ends, July 24; the second begins, July 26, and ends, August 28. Dr. Charles N. Meader, dean.

Connecticut

New Haven School of Physiotherapy, 303 Whitney Avenue, New Haven.—Courses for qualified graduates in medicine. Individual instruction may be had and also practical work on apparatus. The course begins, June 10, and ends, October 1. Dr. Harry Eaton Stewart, director.

District of Columbia

George Washington University Medical School, 1335 H Street, N.W., Washington.—Courses offered for medical students in pathology, bacteriology and clinical microscopy. An opportunity in the laboratory for two or three graduate students who desire to spend their entire time in laboratory work is also offered. Dr. W. C. Borden, Dean.

Howard University School of Medicine, Corner of Fifth and W streets, N.W., Washington.—Courses open to graduates of recognized medical colleges. Instruction given in general surgery, gynecology, genito-urinary surgery, internal medicine, otolaryngology, ophthalmology, roentgenology, public health, laboratory methods and physical diagnosis. Summer term begins, June 7, and ends, July 19. Dr. Edward A. Balloch, dean.

Georgia

Emory University School of Medicine, 98 North Butler Street, Atlanta.—A clinical course is designed for graduates and undergraduates during the first two weeks in July. This course will be entirely clinical, devoted primarily to general medicine and surgery, but with a few things in the specialties which bear particular relation to these subjects. Dr. Russell H. Oppenheimer, dean.

Illinois

Rush Medical College, Wood and Harrison streets, Chicago.—This school has the four quarter system, and therefore the usual summer course is offered to undergraduates. Instruction in otology and laryngology for graduates in medicine is offered and facilities permit of taking but eight men each year, two entering each quarter—January, April, July and October. Dr. Ernest E. Irons, dean.

Loyola University School of Medicine, 706 South Lincoln Street, Chicago.—This school has the four quarter system, and therefore the usual summer course is offered to undergraduates. Dr. Louis D. Moorhead, dean.

University of Illinois College of Medicine, Congress and Honore streets, Chicago.—Postgraduate course for physicians will be offered in all departments throughout the month of June. In some departments the work will be given throughout the day, in others, only half the day. In some fields the courses will be given six days a week, others only three, four or five days a week. Registration will be limited to a small number. The full-time registration fee will be $100, for half-time registration (or less) $50. Mr. William H. Browne, secretary.

Indiana

Indiana University School of Medicine, Indianapolis.—During the summer of 1926, short courses beginning June 10 and lasting for six weeks will be offered to the physicians of Indiana. Instruction given in pathology, pharmacology, medicine, surgery, gynecology, genito-urinary diseases, rhinology, otology, laryngology, ophthalmology and dermatology. For further information apply to the registrar.

Iowa

State University of Iowa College of Medicine, Iowa City.—Courses are offered for undergraduate students in the following departments: anatomy, histology, embryology, biochemistry, physiology and bacteriology. The summer course is for six weeks and a semester's work in any of the subjects mentioned may be completed with the exception of histology and anatomy, in which only a part of a semester's course can be completed. Dr. John McClintock, junior dean.

Kansas

University of Kansas School of Medicine, Lawrence-Kansas City.—Courses for medical students offered at Lawrence in physiology, bacteriology and immunology, and at Kansas City in pathology. Dr. H. R. Wahl, acting dean.

Louisiana

Tulane University School of Medicine, 1551 Canal Street, New Orleans.—Courses offered for medical students in anatomy, embryology, histology, neuro-anatomy, physiologic chemistry, dermatology, special pathology and physical diagnosis. All courses begin, June 14, and continue for a period of six weeks, ending, July 24. Dr. C. C. Bass, dean.

Maryland

University of Maryland School of Medicine, Lombard and Green streets, Baltimore.—A review course for physicians will be offered during the month of June. These courses are not planned and will not serve to enable the practitioner to become a specialist; but it is hoped that they will meet the needs of those who wish to review the fundamental data in some field, and to inform themselves concerning recent advances in methods of diagnosis and treatment. Dr. J. M. H. Rowland, dean.

Massachusetts

Boston University School of Medicine, 80 East Concord Street, Boston.—Dr. William Duncan Reid will offer a one month's course in cardiology either in July or in August at Boston University and associated institutions. Applicants are requested to write Dr. Reid for particulars.

Harvard University Medical School, 240 Longwood Avenue, Boston.—Courses for graduates open from June 1 to September 30, in anatomy, physiology, biologic chemistry, bacteriology, pathology, preventive medicine and hygiene. Dr. Samuel R. Meaker, secretary.

Michigan

University of Michigan Medical School, Ann Arbor.—Courses open to undergraduate students and practitioners of medicine in the following departments: anatomy, bacteriology, dermatology and syphilology, internal medicine, neurology, obstetrics and gynecology, ophthalmology, otolaryngology, pathology, pediatrics, pharmacology, physiologic chemistry, physiology, roentgenology and surgery. Course begins, June 21, and ends, July 30. Dr. Hugh Cabot, dean.

Minnesota

University of Minnesota Medical School, Minneapolis.—This school has the four quarter system, and therefore the usual summer course is offered to both graduate and undergraduate students. Dr. Elias P. Lyon, dean.

Missouri

St. Louis University School of Medicine, 1402 South Grand Avenue, St. Louis.—Work adjusted to needs of three classes of students:

1. Undergraduate medical students. Courses in the laboratory branches are provided, so that students who desire may secure advanced standing or remove deficiencies in work previously taken. Open to both practitioners and undergraduates.

2. Preparatory and collegiate medical students. Courses in biology, inorganic and organic chemistry, physics and language are offered for the benefit of students who desire to attend a medical school but who still lack sufficient college credit to qualify for admission.

3. Teachers, etc. High school teachers and others who do not care for credit in medicine but who possess the required preliminary training will be admitted to the laboratory and other courses.

Session extends from June 1 to July 24. Apply to director of summer school.

Washington University School of Medicine, Euclid Avenue and Kingshighway, St. Louis.—A four weeks' course in obstetrics and diagnostic gynecology for general practitioners will be offered beginning May 24, and extending to June 19. During the first week in each June, September and December a course for practitioners who wish to acquaint themselves with the more recent developments in the study of diseases of the heart and circulation will be offered. Inquiries and applications should be made to the registrar.

Nebraska

University of Nebraska College of Medicine, Forty-Second and Dewey Avenue, Omaha.—Courses offered in physiology and clinical pathology, beginning, June 8. Dispensary and University Hospital assignments for medical college credit in clinical work will be continued. Other courses may be planned if there is a demand on the part of the students. Dr. J. Jay Keegan, dean.

New Jersey

Physiatric Institute, Morristown.—The course, for graduate physicians, gives a practical working knowledge of the management of diabetes, obesity, nephritis, hypertension, etc., according to the methods employed in this institute. The work includes lectures and practical experience in the laboratory, diet kitchen and wards. The tuition is $150 for the one month of full-time work (July 1 to 31). Dr. Frederick M. Allen, director.

New York

Albany Medical College, 58-64 Eagle Street, Albany.—Graduate courses in public health for physicians in conjunction with the New York State Department of Health began in March and will end the latter part of June. It is possible that a course may be repeated in August or September. Communications and applications should be addressed to the director, Dr. Charles C. Duryee, State Department of Health, Albany.

Columbia University College of Physicians and Surgeons, 437 West Fifty-Ninth Street, New York City.—Courses for medical students, offered from July 6 to August 13, in anatomy, bacteriology, cancer research, neurology and practice of medicine. Courses for graduates in medicine are given from June 1 to June 30, in medical diagnosis and pathology; in preventive medicine and public health, from July 6 to August 13; in internal medicine, from June 14 to July 16; in gastro-enterology (lectures, laboratory and clinical work), June, July and August. Dr. William Darrach, dean.

Herman Knapp Memorial Eye Hospital, 500 West Fifty-Seventh Street, New York City.—A course in ophthalmology is offered to qualified medical practitioners which extends over a period of eight months. These courses start, April 1, July 1 and October 1. For further information apply to Dr. Gerald H. Grout, secretary.

New York Eye and Ear Infirmary, Second Avenue, corner Thirteenth Street, New York City.—Courses offered for medical graduates in ophthalmology and otology. Apply to Dr. Webb W. Weeks, secretary, for reservation in the May, June or July classes.

New York Polyclinic Medical School and Hospital, 341-351 West Fiftieth Street, New York City.—Courses for qualified graduates in surgery, gynecology, urology and proctology. Courses may begin at any time. For information address executive officer.

New York Post-Graduate Medical School and Hospital, 301 East Twentieth Street, New York City.—Courses available during the summer term are the same as those offered during the year, open for general practitioners. Dr. William D. Cutter, dean.

Trudeau School of Tuberculosis, Saranac Lake.—A six weeks' course for the intensive study of tuberculosis is being offered, from May 17 to June 26, for recent graduates and hospital interns. Dr. Edward R. Baldwin, director.

University of Buffalo Medical Department, High Street, near Main, Buffalo.—Summer courses for graduates and students are being offered in anatomy beginning July 10, and in chemistry from June 15 to August 1. Dr. C. Sumner Jones, dean.

North Carolina

University of North Carolina School of Medicine, Chapel Hill.—No medical course offered this summer, but one extension course will be offered covering special subjects in general medicine. Further information may be obtained through the dean, Dr. I. H. Manning.

Ohio

Ohio State University College of Medicine, 710 North Park Street, Columbus.—A course in bacteriology and general work in the dispensary are open to advanced undergraduate and graduate students. The summer quarter extends from June 17 to August 28. Dr. Eugene F. McCampbell, dean.

Western Reserve University School of Medicine, 2109-2115 Adelbert Road, Cleveland.—Starting about June 14, a summer course in biochemistry will be offered to undergraduates for make-up work. Course not given unless a certain number apply. Students from other schools admitted when feasible. Dr. Carl A. Hamann, dean.

Pennsylvania

University of Pennsylvania Graduate School of Medicine, Philadelphia.—Courses for graduates, during the summer months, in various hospitals and institutions offered in conjunction with the graduate school are as follows: cardiology, May 3 to June 26 and August 30 to October 23; gastro-enterology, May 24 to July 2; operative surgery and surgical anatomy, April 19 to June 12; laryngoscopy, bronchoscopy and esophagoscopy, June 7 to June 19. Dr. George H. Meeker, dean.

University of Pittsburgh School of Medicine, Bigelow Boulevard, Pittsburgh.—Postgraduate course for general practitioners begins, June 1, and ends, June 12. Address all communications to Edith S. Glenn, secretary.

Texas

Baylor University College of Medicine, 720 College Avenue, Dallas.—Work adjusted to needs of three classes:

1. Undergraduates and special students. Regular medical college courses, for which subject credit is given, is offered from June 14 to August 1.

2. Summer clinics for practitioners. These clinics are of a general character and extend from May 31 to June 12. No fees are charged nor are any certificates of attendance granted.

3. Public health course. This course is primarily for county and city health officers, and extends from May 31 to June 12, inclusive. No fees are charged, nor are any certificates of attendance granted. Dr. Walter H. Mouraund, dean.

University of Texas School of Medicine, Avenue B, between Ninth and Tenth streets, Galveston.—Summer clinics in all clinical subjects, including ward cases, obstetric practice and outpatient clinics, open to students of the medical school of the University of Texas from May 24 to June 5. Dr. William Keiller, dean.

West Virginia

West Virginia University School of Medicine, Morgantown.—Courses offered to undergraduate students in (gross) anatomy, including neurology, histology, physiologic chemistry and bacteriology, during the summer term of twelve weeks, which begins, June 21. Dr. John N. Simpson, dean.

Virginia

University of Virginia Department of Medicine, Charlottesville, Va.—Courses in the medical sciences are being offered during the summer for medical students who are deficient in these subjects and desire to make a review: Group A, histology and embryology. Group B, anatomy, topographic anatomy and anatomy of the human nervous system. Group C, biochemistry. Group D, pharmacology. Courses will not be given unless a certain number apply. Dr. James C. Filippin, acting dean.

Wisconsin

University of Wisconsin Medical School, Madison.—Summer courses open to undergraduate students from June 23 to August 6 in anatomy, bacteriology, hygiene, medicine, pharmacology, physiologic chemistry and physiology. Dr. Charles R. Bardeen, dean.

Wisconsin January Examination

Dr. Robert E. Flynn, secretary of the Wisconsin Board of Medical Examiners, reports the written examination held in Madison, Jan. 12-14, 1926. The examination covered 18 subjects and included 100 questions. An average of 75 per cent was required to pass. Of the 22 candidates examined, 20, including 4 osteopaths, passed and 2, including 1 osteopath, failed. Seven candidates were licensed by reciprocity. The following colleges were represented:

PASSED

Social Medicine and Medical Economics

SOCIAL MEDICINE

A Method of Teaching the Public Health Point of View to the Medical Student

B. FRANKLIN ROYER, M.D, SC D
Medical Director, National Committee for the Prevention of Blindness
New York

About three and a half years ago a symposium on "The Next Step for State Health Departments" was conducted as a special session of the annual meeting of the American Public Health Association in Cleveland. Five distinguished state health officers presented their individual views in formal papers. The five authors left the impression with the audience that the medical profession, both the highly organized and the less well organized, was not approvingly cooperative and in some instances was openly antagonistic to public health work except of the police type, and was fearful of state medicine. The chairman of the meeting, Dr. John Dill Robertson, health officer of Chicago, challenged me, then executive officer of the Massachusetts-Halifax Health Commission, to state what the next step would be in Nova Scotia. When thus challenged by the chairman, I developed the thought that public health executives and teachers of hygiene in medical schools had heretofore failed to teach the medical student the right point of view toward social medicine and public health.

The plans and methods outlined extemporaneously were at that time in existence for the most part as a paper agreement only between Dalhousie University, Halifax, Nova Scotia, and the International Health Board, then representing Mr. John D. Rockefeller in distributing certain personal gifts for improving medical education in Canada. Enumeration was given of the organizations cooperating with the university in its medical teaching, as follows: one large general hospital, a children's hospital, two specialized hospitals, one for tuberculosis and one for maternity work all grouped about the medical school, a philanthropically maintained public dispensary of the usual type operating in a building some distance across the city, and the Massachusetts-Halifax Health Commission. All of these related institutions indicated a disposition to favor a special health center building if built in the university and hospital area from funds provided by Mr. Rockefeller.

The plan as outlined consisted of the erection of a special building[1] at the cost of a quarter of a million dollars, to be laid out for the accommodation of all public health clinics and of the curative medicine ambulatory clinics that might be required for a community already numbering 60,000 people. The hospitals, it was hoped, would in future refrain from developing outpatient dispensaries. The old Halifax Dispensary agreed to close its old building, move into this new building, and coordinate its activities (without losing its identity) with those services to be conducted under the Medical Department of Dalhousie University in the new health center building The general social agencies of the city and the unofficial special health agencies operating in the south half of the city of Halifax and those that might develop around the hospitals would be offered headquarters in this new health center building.

The city health department, as then represented on the Massachusetts-Halifax Health Commission, fully understood the scheme, and the commission was expected to provide socially trained public health nurses and visiting housekeepers to cover every family patronizing the new health center It was likely that the commission would meet operating costs of the various public health clinics for several years. It was expected that well baby, preschool age guidance, preschool age dental clinics, nutrition classes, posture services and diagnostic chest clinics would be included in this health center, and that the commission might assist the partially subsidized venereal disease clinic.

The Dalhousie University medical school, it was understood, would furnish all medical personnel and organize and maintain the full quota of outpatient department and ambulatory services, such as pediatric, general medicine, surgical, neurologic (including psychiatric) and, as soon as practicable, metabolic and such other services as might be required.

It was understood that there should be a close "tie-in" of all activities of this new building with the department of preventive medicine, and that the professor of this branch (hygiene and preventive medicine) should have an opportunity to exact of the medical student a complete home environmental study and habit study of assigned ambulatory cases carefully examined by him in the clinic building.

It was anticipated in this discussion that physical diagnosis and medical teaching would probably be carried on both in the public health clinics and in the curative medicine clinics, and that a student's studies would not be considered complete unless they included home visits and home studies covering every detail of living, diet, exercise, sleep, ventilation, clothing, and the thousand and one types of error and exasperation found in the home; that an opportunity would be afforded in this building for the student of medicine to bring his written report of the home environment and recommendations to the desk of the professor of hygiene and preventive medicine; and that this university teacher could have as a check-up against the student's hygiene study the complete environmental report of the well trained public health nurse, social worker or visiting housekeeper assigned to cover families patronizing the public health clinics and the curative medicine clinics.

It was even hinted in this extemporaneous discussion that the final grades to be given on hygiene and preventive medicine might advantageously be based on the practical application of the student's knowledge to these environmental studies and his recommendations based on them.

It was pointed out that such practical methods in teaching applied hygiene and preventive medicine would compare favorably with application of principles to practice in the other departments of a medical school. The didactic instruction in medicine, surgery, pathology, etc., is followed by practical application of these principles at the bedside, in the surgical clinic, or in the postmortem room.

The department of hygiene and preventive medicine may with such a plan supplement the didactic instruction of this department with equally practical applied lessons, and utilize the grades thereon as a final grade.

---

[1] An illustrated article by Dr. William Harop Hattie on "Teaching Medical Students Newer Public Health Work," published in Nation's Health, June 15, 1924, shows plans of the health center building and gives some operation plans A second article by the same author published in Modern Hospital, August, 1925, on "Public Health Clinic Correlates Preventive and Curative Practice," discusses this new coordinated effort

Such an application would be new in medical teaching and would seem to give the medical student a practical view of applied social medicine as every physician should apply it.

The plan, as presented extemporaneously in Cleveland in 1922, materialized practically as outlined, and became operative in November, 1924. Dr. William H. Hattie, who for five years had been Nova Scotia's provincial health officer, and lecturer on hygiene and preventive medicine in the medical school of the university, resigned from his provincial position and gave full time to teaching work. His university chair was extended to include that of director of the newly erected health center building prior to its equipment.

For a year following the opening of this new building, Dr. Hattie has been watching the students of medicine with their opportunities to gradually become socially minded. He can watch the student who, until recently, had scant grasp of the influence of environment, reach the stage at which he recognizes how much of the condition that brought the patient to the clinic was due to environmental fault, and can see the student realize that in many instances medical problems may be corrected only by giving intense attention to environmental faults.

Dalhousie University is blazing a new trail in preventive medicine. Dr. Hattie is giving the students who pass his chair an opportunity to see that social medicine is far from being state medicine; in fact, is opposed to state medicine. He is making the young practitioner appreciate that physical examination of the patient and writing of a prescription for a drug are, after all, the smallest part of the sum total of the practice of medicine.

Dalhousie University's school of medicine is in a position to send out through the three maritime provinces practitioners of medicine who will have no fear of state medicine, but who will serve as the real leaven in their communities to stimulate and arouse those various social activities which, when coordinated with executive health work, will multiply the effects of public health endeavor manyfold. This new departure in teaching social medicine will be followed with great interest and is likely to be adopted in all progressive universities.

370 Seventh Avenue.

Book Notices

Aviation Medicine. By Louis Hopewell Bauer, A.B., M.D., Major, Medical Corps; United States Army Commandant, the School of Aviation Medicine. Published by authority of the Surgeon General. Cloth. Price, $7.50. Pp. 241, with 35 illustrations. Baltimore: Williams & Wilkins Company, 1926.

The flight surgeon is destined to become second only to the commanding officer in the training and care of any aviation unit, and his great value to civil aeronautics will become indispensable as the larger companies are organized for the transportation of mail, express, freight and passengers. Little of originality is claimed by the author of this book, but he has endeavored to correlate the results of the many workers in their respective fields in such a way that the book will be of value not only to the flight surgeon, the student of aviation medicine and the recruiting air officer, but to the general medical man in all walks of life. The book is divided into three sections, each containing approximately sixty pages, and a supplement. The first section gives the qualifications of a flier. At present the best fliers are between the ages of 20 and 28. Those under 20 usually lack good judgment, while those over 35 should be taught only as administrative officers. Physically, the applicant should be well proportioned, while good eyesight is one of the most important prerequisites. Twenty twentieths is not too high, although twenty thirtieths in each eye may not disqualify. Judgment of distance and deep perception depends on good eyesight, and the applicant should have good peripheral vision and normal color vision. Latent hyperopia, heterophoria and night blindness should absolutely disqualify. The nose and throat should be free from disease and the ear should receive especial attention, particularly the drum, middle ear, eustachian tubes and hearing. Equilibrium, which plays an important part in flying, is governed by the whole proprioceptive mechanism. Vision, the vestibular mechanism and the indefinite "muscle sense" or "feel of the seat" are of importance. Nervous stability is an important factor, since the flier is subjected to unusual culminative stresses. The psychoses and psychoneuroses and even the family history may have an important bearing on the ability of the man to retain his nervous stability, while his own history should be obtained with the greatest care.

The second section considers the physiology of aviation, including the classification of the fliers. The author goes into the physiology of the respiratory and circulatory systems at sea level and at the higher altitudes, giving not only the change in hemoglobin, red cells and white cells, which is due to the lack of oxygen, but also the changes in the metabolic rate. Facts and figures prove that between 40,000 and 45,000 feet it is almost impossible for a human being to live, even though he is breathing pure oxygen, for beyond this point the available oxygen pressure in the lungs will be too low to sustain life. The heart at high altitudes is at no greater strain than the rest of the circulatory system. With a normal heart accompanied by soft arteries, the effects of altitude will not be lasting on either, as recovery is prompt on the administration of oxygen. Psychologically, the effects of altitude come on the aviator unawares: stimulation, followed by a feeling of well being, then decrease in attention and loss of muscle control. Altitude classification is rather difficult but is now being done with much success in the air service. Wind, cold and speed all have their deleterious effects on the aviator. To wind may be ascribed an increase in metabolism, with increased demand for oxygen; difficult breathing, and cooling of the body. Cold brings on stiffness, chilling and a tendency to sleepiness, and stimulates metabolism and the demand for more oxygen. Speed, especially the centrifugal force at curves, tends to cause anemia of the brain, with consequent haziness, laziness, dizziness and perhaps unconsciousness. Recovery is prompt.

The third section is devoted to the care and maintenance of the flier. Since great care is exercised in his selection and classification, even greater care should be exercised in keeping him fit, since the past has proved that deterioration is the natural tendency of all fliers. Fatigue may be brought on by too many hours of flying and by altitudes above 15,000 feet. Staleness and nervous exhaustion depend on habits and temperament of the individual, the type of machine and work, weather conditions, and the environment of the airdrome. Too much or too little flying, insufficient exercise, dissipation and loss of sleep have the same effect. The author believes that definite condition develops in a flier as a result of his air work. Mental and physical signs and symptoms are closely associated with "effort syndrome," nervous fatigue, distress on exertion, loss of interest in his work, poor muscular control, inattention and carelessness. Effort syndrome is an overresponse of the circulatory and respiratory systems to physical efforts, marked by breathlessness increased on exercise, precordial pain increased by exercise, exhaustion, mental and physical, palpitation, giddiness, even fainting, headache, lassitude, irritability, sleeplessness, inattention, cold hands and feet, and sweating of the hands, feet and axillae. This condition must be caught in its incipience by the flight surgeon in order to save a good flier and avoid a serious accident.

Chapter 13 describes the protective devices and their uses; the oxygen supply apparatus, the gas apparatus, liquid oxygen, the amount of oxygen required at certain given altitudes, masks, goggles, ear protection, helmets, parachutes, belts and clothing, giving in detail the best articles for use of the present day flier.

Special training is necessary to become a flight surgeon. He must first be well grounded in internal medicine, and in addition must have some knowledge of physiology, psychology, ophthalmology and otology. He must be able to inspire confidence not only in the commanding officer, but also in the men under his care. He must actually live with his fliers and learn their inner life and must be able to recognize staleness, fatigue and physical unfitness in its incipience He is both physician and trainer and his duties are quite different from those of a medical officer in any other branch of the service. The flight surgeon should actually fly in all sorts of weather, in different types of machine, across the country, and on acrobatic and altitude flights, so he may obtain a better insight into the life of his fliers. The civil flight surgeon is something yet to develop, but surely will be needed in the near future.

Chapter 15 is devoted to "Aviation Accidents and Their Prevention by the Flight Surgeon" so far as the pilot is concerned He must weed out the unfit, the careless and the mentally and physically sick and thus prevent accidents This chapter also covers the airplane ambulance, which it describes with its many uses, while chapter 16 gives a brief outline of the causes of dope poisoning by its various ingredients Tetrachlorethane, which gives rise to toxic jaundice, is now very seldom used. Methyl, ethyl and benzyl acetate, which cause anemia, vomiting, fever and fatty degeneration of the endothelium of the blood vessels, are among the other ingredients of dope. Proper methods of treatment are also discussed

The final chapter is devoted to civil aviation. At the present time there is no federal legislation governing aviation This is a ridiculous situation, since a pilot rejected as unfit, either physically or mentally, by the government, may hire a plane and fly, thus endangering not only himself, but others and property. Requirements for civil aviation need not be as strict as for the air service but should receive careful attention when an adequate federal law is passed, and should require a medical examination at least once every six months. In this chapter standard forms for a medical certificate are described, while in the supplement may be seen the directions for Schneider's test for circulatory efficiency; blanks for the rebreathing examination; the pulse and blood pressure determination; directions to the clinician, the psychologist and the pilot; low oxygen tension, and physical examination for flying. All the chapters are extensively illustrated and show the latest apparatus used in the United States Army.

The Nematode Parasites of Vertebrates. By Warrington Yorke, M D, Professor of Parasitology, University of Liverpool and Liverpool School of Tropical Medicine, and P. A. Maplestone, M D, D S O. With a foreword by C. W Stiles, Professor of Zoology, United States Public Health Service. Cloth. Price, $9 Pp. 536, with 307 illustrations. Philadelphia: P. Blakiston's Son & Co., 1926.

In the sixty years since the appearance of Schneider's monograph, the fragmentary and scattered contributions on the roundworms, of which there have appeared a very large number, have been in need of interpretation and correction In the closely printed pages of this book are compressed a synopsis of the eight superfamilies recognized by the authors, a record of inadequately known and hence entirely unclassifiable genera, several briefer valuable lists, full indexes of generic and specific names, and finally a list of 684 articles cited in the text. The synopsis, which covers about 440 pages of the book, gives a succinct description of all known genera, including some that were necessitated by the work itself. The illustrations include more than a thousand sketches, most of which are new and all of which are good. To enter here into a critical analysis of results so extensive is impossible. That the details will excite criticism is a merit. Now for the first time biologists have a clear basis on which to work The book shows that the study has been carried on primarily in the laboratory and on the specimens themselves. In consequence, it possesses permanent value In view of the importance of *Nematoda* in human and comparative pathology, the medical worker will find this volume of marked service.

Eine Studie uber Krämpfe (A Study of Convulsions) Von J. Hughlings Jackson Uebersetzt und eingeleitet von Otto Sittig Paper. Price, 8 40 marks Pp. 145 Berlin: S Karger, 1926

The importance of Dr. Jackson's contributions to medical literature has long been recognized. The German publishers here make available a reprint of his original paper with a German translation on opposite pages.

Expert Testimony—Statements to Examining Surgeon

(Johnson v. Bangor Ry. & Electric Co. (Me.), 131 Atl. R. 1)

The Supreme Judicial Court of Maine, in overruling the defendant's motion for a new trial after the plaintiff had obtained a verdict for damages for personal injuries, says that it was contended that the evidence so greatly preponderated in favor of the defendant that the court should be satisfied that the jury manifestly had erred, and that the damages were excessive. The argument was confined largely to the proposition that the jury had not given sufficient weight to the medical testimony in the light of the plaintiff's condition before the accident. It was conceded by medical experts on both sides that at the date of the injury the plaintiff was suffering from arthritis deformans. Still the writ alleged, and the medical testimony for the plaintiff tended to show, that he had sustained a fracture of the tenth dorsal vertebra. But the witnesses for the defendant denied that there were any indications of such fracture, and the defendant contended that the plaintiff had suffered no permanent injuries on account of the accident.

In considering a case so presented, it must be borne in mind that the testimony of the expert witnesses is only an expression of opinion, and is received on the theory that their special learning and skill may render their opinions of service to the jury; that thus the jury may obtain some assistance not otherwise available. The evidence may be stated as an assertion in the negative, as when a witness, examining a roentgen-ray film of the plaintiff's back, taken by another than the witness, asserts that he perceives no indication of a fracture; yet the testimony is but the expression of the witness' opinion, his interpretation of what this highly scientific aid to diagnosis shows; and its accuracy, or the weight to be given to it, is quite dependent on the skill of the operator who took the film, and the clearness which he obtained, as well as on the witness' own scientific skill. The assistance which testimony of this character—the court refers to expert testimony in general—may afford is, like other testimony, wholly for the consideration of the jury. The members of the jury may fairly come to the conclusion that none of it, or a part only, is entitled to weight in their deliberations. The testimony in this case well illustrated the limitations in the value of testimony of this kind. It was apparent that, after listening to the extended recital of the views of the expert witnesses, the jury did not lose sight of the fact that the plaintiff was seriously injured, a fact which it was fully justified in finding, without undertaking to determine the precise injury, if it believed the evidence submitted in his behalf. So finding, this court cannot say that the jury manifestly erred in the award of damages.

A witness called as an expert surgeon to testify in behalf of the plaintiff had examined the latter at the request of his attorneys in order to give an opinion relative to his injuries. The witness was allowed to state: "He described his accident, much as he has here. . . . Mr. Johnson's accident, as he described it to me, had been one in which he had been pitched onto his head and shoulders and his legs had been doubled up. . . ." The defendant objected to the admission of what the plaintiff told the surgeon relative to the happening of the accident, on the ground that the plaintiff's statement of such matters to the surgeon, who was examining him with a view to testifying as an expert witness and not for the purpose of treatment, was not admissible in evidence; but the evidence was admitted subject to the objection. It may be assumed that the surgeon's examination was made at some time subsequent to the injury, and that whatever the plaintiff said to him was narrative of a past event. Such statements by the plaintiff were clearly inadmissible as evidence of the facts stated. But it was very clear that the surgeon did not make the statements objected to for any such purpose. He examined the plaintiff that he might be in a position to give an opinion as to his injuries. It was very desirable, perhaps necessary, that he should obtain a history of the case. If the history which he obtained coincided with the facts as proved by competent evidence, his opinion would be entitled to a certain degree of weight; if his opinion was based on an erroneous history of the case, the basis of his opinion fell, and his opinion became of less weight. The exception, which is overruled, did not disclose an instance in which the plaintiff was endeavoring to support his case by incompetent evidence of the substantive fact which he alleged, under the guise of fortifying the opinion of an expert.

Death from Peritonitis After Injury to Hip and Leg

(Martin's Case (Me.), 130 Atl. R. 857)

The Supreme Judicial Court of Maine, in dismissing an appeal from an award of compensation by the chairman of the industrial accident commission, says that the husband of the claimant fell and received one or more traumatic injuries. Later, peritonitis developed, from which death resulted. The injuries set forth by the claimant in her petition as having resulted from the accident were to the hip. The evidence, however, also disclosed a cut or abrasion below the knee. There was no open wound at the hip. Against the award it was urged that it was not made sufficiently clear by the evidence to take it out of the realm of conjecture that the peritonitis, which was the immediate cause of death, was the result of the accident and not of disease. However, two reputable physicians, who attended the man during the last three weeks before his death while in a hospital, and who made careful examinations to determine the nature of the infection, performing an abdominal operation and after death a necropsy, gave as their unqualified opinion that the infection was not the result of typhoid fever or of other so-called internal causes, but was the direct result of the accidental injuries received. It may appear to the layman that the inference that the infection resulted from the injury to the hip was not a reasonable one, as there was no open wound as a source of infection; but one of the attending physicians gave it as his opinion that the injury below the knee was the original source of the infection. The case, however, was fully heard on evidence as to both injuries and their relation to the infection which resulted in the employee's death, and the court thinks that the chairman's findings had some competent evidence to support them, wherefore the appeal was dismissed.

Evidence Concerning Abortion by Former Physician

(Max v. People (Colo.), 240 Pac. R. 697)

The Supreme Court of Colorado, in affirming a judgment of conviction of defendant Max, says that he was sentenced to the penitentiary for a term of not less than twenty nor more than thirty years on a verdict of guilty of second-degree murder committed by performing an abortion which caused the death of a certain girl. He contended that there had been an erroneous admission of evidence. But to the general rule that evidence of independent crimes is inadmissible there are certain well recognized exceptions, one of which is that such evidence is admissible to show intent. Nor does the court know of any such rule in Colorado as that such evidence is inadmissible because it is the rule in the state that exceptions in a criminal statute need not be negatived. The mere fact that the people are not required to negative the exceptions does not make it error for them to do so, either in the charge or in the proof. Hence the admission of evidence that the defendant performed an abortion on another person ten days before he performed the one in question was proper to prove intent.

Another exception to the general rule is recognized when the plan or design of the accused is material because the specific act charged is a part of such plan or design and the proof of the latter has a strong tendency to establish the former. This defendant was charged with abortion, an offense ordinarily committed by one having some skill in certain branches of surgery. He had been admitted to practice, and had practiced medicine and surgery, and presumably had the required skill. His license had been revoked for the very offense here charged. Years afterward he was found still in the city, maintaining an office with equipment for practice, and especially equipped to perform abortions, and only a few days before the date alleged in the information he was found committing the same kind of crime The court thinks that the instant case thus clearly came within the exception which permits the proof of other offenses to show plan or design.

Under another general rule, mere memoranda are inadmissible in evidence, but an exception to this rule is recognized when such memoranda form part of the transaction which they tend to characterize and explain, and thus become a part of the res gestae (essential circumstances of the case) Therefore, when the defendant, in preparing to meet the charge against him, employed a man to manufacture evidence and the man, in the course of that employment, kept memoranda relating to the defendant's instructions to him, his execution thereof, and his reports thereon, the memoranda were admissible in evidence as a part of the res gestae of the conspiracy which the people were presenting to the jury as a part of their proof of the defendant's guilt. Then, most of the evidence of preparation for the abortion and the visit of the girl to the office of the defendant on the date in question for the purpose of its performance was given by a woman with whom the girl lived, and consisted principally of the recitation by the witness of statements made to her by the girl. This evidence was clearly admissible.

The admission of evidence that the defendant's license to practice medicine had been taken from him and not restored was said by his counsel to be an attack on his character, and prejudicial error, because the defendant had not put his character in issue. This evidence was offered generally, and the only objection to it was that it was incompetent, irrelevant and immaterial. Hence, if admissible for any purpose, there was no error. If this court is correct in its first conclusion, then this evidence was admissible to negative the statutory exceptions, being proof that the defendant, if he performed the operation, could not have done so as "a physician or surgeon." Moreover, the very fact that one who keeps a physician's and surgeon's office, equipped with surgical instruments, especially instruments used in procuring abortions, and is visited by women seeking that service, has been a practicing physician and surgeon, but has been deprived of his license because of an illegal abortion, is, in the light of the established facts in the instant case, evidence tending to prove guilt. This office, these instruments, the other abortion referred to, the visit and purpose of the girl, all might be innocent of offense if relating to the conduct of one lawfully practicing medicine and surgery; but, relating to the conduct of one lawfully prohibited therefrom, they spell crime.

Taxation of Hospital's Separate Home for Nurses

(Johnson v. Mississippi Baptist Hospital (Miss.), 106 So. R. 1)

The Supreme Court of Mississippi, division B, in reversing a decree rendered for the complainant hospital, says that it was error to overrule the demurrer which Johnson, city tax collector, filed to the bill in which the complainant asked for an injunction against him to prevent a sale for taxes of certain lots on which was situated a house owned by the complainant and used in housing nurses in the employment of the hospital. Section 4251 of the code of 1906 provides that the following property shall be exempt from taxation: "(*d*) all property, real or personal, belonging to any religious or charitable society, and used exclusively for the purpose of such society and not for profit"; "(*f*) property appropriated to and occupied and used for any hospital or charitable institution." But when a hospital maintains a home for nurses who are employed in the service of the hospital, where they live when not on duty, which home for nurses is situated on a separate lot or on separate lots from that on which the "hospital" building is located, and such home for nurses is not used exclusively for the purposes of such hospital within the meaning of section 4251 (*d*), such property is subject to taxation. Nor is such property, used as a home for nurses, exempt from taxation under section 4251 (*f*).

Furthermore, although the hospital gives to such nurses employed by it a course of instruction in the proper nursing and treatment of patients, such property, used as a home for nurses, is not exempt from taxation under section 4252, which provides that all the property belonging to any religious or charitable society, where no dividends are declared and where the revenues thereof are used for benevolent purposes, shall be exempt from all state county and municipal taxes. Nor is such property used as a home for nurses, exempt from taxation under the provision of chapter 134 of the laws of 1922 that all property belonging to religious or charitable or benevolent organizations, which is used for hospital purposes and which maintains one or more charity wards that are for charity patients, and where all the income from said hospital is used entirely for the purposes thereof and no part of the same for profit, shall be exempt from all taxation.

In this court's view, the maintaining of a home for the nurses employed by the hospital and for other employees of the hospital is not a hospital purpose within the meaning of the statute The statute contemplates such uses as are reasonably necessary to an effective discharge of the powers and duties of the hospital under its charter powers. It is not necessary, for the proper operation of a hospital, that the corporation should furnish homes for the nurses when not on duty They are no different from other people who work and pay for board and lodging or furnish their own homes when off duty and performing no service necessary for the proper operation of a hospital. It would be an unwarranted distinction, by construction of the language of the statute, to hold that buildings used merely as a rooming house for employees come within the meaning of the statute. Therefore the court is of the opinion that the home for nurses and the lots on which it is situated, here under consideration, are subject to taxation.

Expenses of Health Officers in Attending Conventions

(Miller, State Revenue Agent, v. Tucker et al (Miss), 105 So. R. 774)

The Supreme Court of Mississippi says that the state revenue agent sued the defendants as members of the board of supervisors of Warren County to recover, on their several bonds, various amounts alleged to have been paid by the board without legal authority therefor. One item involved was an allowance of $222.26 to a physician, in December, 1920, as county health officer, for a trip to Washington to attend some meeting of a professional nature there. It was contended by the defendants that the warrant was properly allowed to the physician because it fell under the jurisdiction of the board under that clause giving the board jurisdiction "of all matters of county police" The court, however, thinks that the chancellor properly allowed the revenue agent to recover this item, and it affirms his action in reference thereto. The board of supervisors have no authority to pay the county health officer's expenses in attending conventions outside the county, and the board of supervisors are liable on their bond for an allowance for such officer for such purpose.

"Entirely Without Understanding"

(Fleming v. Consolidated Motor Sales Co. et al. (Mont.), 240 Pac. R. 376)

The Supreme Court of Montana says that the phrase "entirely without understanding," as used in section 5683 of the code of that state, which provides that "a person entirely without understanding has no power to make a contract of any kind," is construed, not as requiring proof of an entire lack of understanding on any subject, i. e., that the mind of the person is an absolute void, but such a degree of mental deficiency as to render him incapable of understanding a transaction of the nature involved. Proof that a person is of "unsound mind" is not sufficient to establish that he is "entirely without understanding," as the phrase is interpreted. Furthermore, if the purchase of a car which he did not need would brand a person as one "entirely without understanding," most of us have placed ourselves in the same category. In the absence of entire lack of understanding, and in the absence of fraud or imposition, there is no degree of mental weakness on the part of either of the contracting parties recognized in the law as vitiating a contract. The law does not presume to make a distinction between much and little intellect.

West Virginia State Medical Association, Morgantown, May 25 27. Mr S. O. Neale, 211 Smallridge Building, Charleston, Executive Secretary.

MEDICAL SOCIETY OF THE STATE OF NEW YORK

One Hundred and Twentieth Annual Meeting, held at New York, March 30 April 1, 1926

(Continued from page 1478)

Etiology of Postoperative Pneumonitis

DR ALLEN O. WHIPPLE, New York: There are three fairly well defined pathologic processes in the production of postoperative pulmonary complications: (1) aspiration of infected secretions; (2) pulmonary infarction, and (3) atelectasis. No one of these three processes can be considered as the sole etiologic factor. In 1915-1916, at the Presbyterian Hospital, the incidence of pneumonitis was 2 3 per cent in 3,217 operative cases; in 1924 it was 2 per cent, and in 1925 it was 1.4 per cent. This is in large measure due to the fact that we have advised consistently against abdominal operations during the late winter and spring when respiratory infections are most prevalent. These figrues show that elimination of respiratory infection before the abdominal operation is not to be overlooked.

DISCUSSION

DR. WILLIAM D. JOHNSON, Batavia, N. Y.: With regard to the factors in the production of postoperative pulmonary complications, I feel just the way Dr. Whipple does, that no one thing is to be given great predominant consideration. If a patient comes in who has been in the habit of wearing his underwear to bed, we will let him do it. Many years ago I was told that the way to avoid postoperative pneumonia was to put on a mustard plaster as soon as the patient was back in bed, and that is routine. In every case of abdominal operation a jacket of mustard is put on until the skin gets as red as a baby's lips. The portable roentgen-ray machine will tell if there is massive collapse of the lung, which occurs in a greater percentage of cases than one thinks. We have made it a routine to make a roentgen-ray examination with the portable machine as soon as the patient is awake in cases in which we suspect massive collapse. The patient with actual massive collapse of the lungs is got up into a chair within twenty-four hours of the time of the operation and made to breathe deeply. My anesthetist is afraid of deep anesthesia, and I of light anesthesia. As a result of all these things, we have not had a case of massive collapse in the last year. Prevention is the important thing.

DR. WILLY MEYER, New York: One of the elements causing postoperative pneumonitis and very frequently death is aspiration, which occurs sometimes during operation even in the hands of an expert, and particularly toward the end of the operation and right after it during the return of the patient to bed. For many years we have insisted on placing the patient on the stretcher in a pronounced Sims posture. When he then vomits, aspiration cannot occur; the gastric contents must run out the lower angle of the mouth. The patient is placed in the same position in bed, provided there is no contraindication. In Bier's surgical clinic in Berlin, investigation has been made on patients suspected of developing lung complications. They take 8 minims (0 5 cc.) of ether, mix it with 8 minims of sterile oil and a few drops of a local analgesic, and inject it into the gluteal muscles once in twenty-four hours, from three to five days in all. As in colonic anesthesia, the ether is bound up with oil and given off slowly in the body—a better procedure than to inject plain ether. The result is a mild hyperemia of the bronchial mucosa, which represents the curative agent. Of 187 patients just beginning to show lung complications, 185 did not develop pneumonia.

DR. HENRY KELLER, New York: One of the important measures in the treatment of postoperative pneumonitis, as well as an effective preventive of pneumonitis as a postoperative complication, is the application of diathermy to the chest region. In robust patients the diathermy pads can be applied soon after the operation is completed, and as soon as the patient is returned to bed the pads and the application of the current can be continued for a number of hours. On the other hand, in cases considered bad surgical risks, the application of diathermy can be commenced prior to the operation, and continued during the operation and for a number of hours following the operation.

DR. JOHN A. LICHTY, Clifton Springs, N. Y.: In considering cases of postoperative pneumonitis there should be active team work on the part of surgeon, internist and pathologist. I believe that the diagnosis of postoperative pneumonitis is made more frequently than it should be. Statistics on postoperative pneumonitis are misleading unless the diagnosis is verified by a necropsy. With reference to the prophylactic treatment against postoperative pneumonia, the suggestions given by Dr. Whipple and Dr. Johnson are interesting and yet I believe it is difficult to determine just how much good all these procedures and findings accomplish, largely because in the various epidemics of colds, grip, etc., which are characterized by the frequency of postoperative pneumonitis, the character of the micro-organisms differs. Any measures that might have to be instituted when the epidemic is mild might show good results, whereas a much better method instituted when the epidemic is severe might not give as good results as it would otherwise.

Dr. Malcolm Rose, New York: Drowning people with ether has a good deal to do with putting their lungs in good condition for the development of pneumonia.

Dr. Allen O. Whipple, New York: An important prophylactic measure to be used against the development of pulmonary emboli is careful handling of the tissues, avoiding injury of the large venous channels in such areas as the rectus muscle. I agree that the majority of statistics on the subject are not of a great deal of use. I am glad to hear that you cannot demonstrate all these cases by necropsy. I think ether has been blamed entirely too much for these complications and that the term "ether pneumonia" is a misnomer.

Pulmonary Abscess and Its Treatment

FROM THE SURGICAL STANDPOINT

Dr. Adrian V. S. Lambert, New York: The crux of the successful treatment of lung abscess may be summed up by the one word drainage, and in the management of any given case the problem is to effect adequate drainage. In our entire series of cases about 50 per cent of the patients recovered completely under the more conservative forms of treatment without operation. The exact time at which to drain a lung abscess through the chest wall is when the zone of exudative inflammation has been reduced to a minimum and the central cavity is surrounded by a series of collapsed vesicles, representing a more or less discrete wall. It is most important to establish its exact location with accuracy and, if possible, the point at which it is nearest the chest wall. Abscesses situated near the hilum are the most difficult to drain by incision, but fortunately recovery usually occurs without operation. The use of the aspirating needle on the unopened chest in order to establish the diagnosis is an unjustifiable procedure, because of the danger of establishing an empyema. After the abscess has been opened, it should be explored with the finger and the opening enlarged so that the drainage may be placed at its most dependent portion. As a drain I use a collapsed cigaret drain covering without any contained gauze and place a rubber tube of large caliber and soft texture just inside the abscess wall, leading the cigaret covering to the surface through its lumen. The incisions of the superficial layers of the chest wall are packed with iodoform gauze about the tube. This acts as an excellent protective against infection. The patient is kept on his operated side until he has completely established his respiratory equilibrium and emptied his bronchial tree of contained secretion. Drainage must be maintained until the roentgen ray shows a complete clearing of the surrounding lung and a granulating tract is established.

FROM THE MEDICAL STANDPOINT

Dr. James Alexander Miller, New York: In the treatment of pulmonary abscess, absolute rest is extremely important, not only during the time when the patient has fever, but afterward. Within a week or so, if the patient is in bed, even though the amount of expectoration is considerable, the fever will subside and the patient is better. This rest in bed during the whole period of the suppurative process is of extreme importance. While the patient is kept at rest, we try to facilitate drainage by the use of posture. We invert our patients over the foot of the bed, with the hands on the floor, so that the abscess side is up. The logical position is not always the one in which the patient drains best, and we have to experiment to find which is the best way. A patient will be relieved for several hours by emptying the abscess by this posture. This is carried out three or four times a day. This, in connection with absolute rest in between, is our fundamental treatment for a period of time sufficient to demonstrate whether or not additional methods are necessary to cure the patient. If the patient does not do well on a regimen of rest and posture, the question of bronchoscopy is considered. We do not agree that bronchoscopy is in all cases of abscess the method that should be tried immediately, because it is not as simple and harmless a thing as it is sometimes described to be. Another method of treatment which we have used and which is widely discussed in the literature is artificial pneumothorax. We have not had favorable results with it in pulmonary abscess. The treatment may do real harm either by rupturing adhesions, and thus causing acute empyema, or by compressing the draining bronchus, thus cutting off the drainage.

DISCUSSION

Dr. Howard Lilienthal, New York: It may possibly be necessary in treating multiple abscesses of the lung to use thoracoplasty. Fifty per cent of these patients will get well spontaneously, but the remaining 50 per cent will die if not operated on, and operated on at the right time. But this does not mean that the ordinary lung abscess is a question of an emergency. It usually is not. If one makes the diagnosis before there is a bronchial connection, and then operates, the patient will recover very promptly, because every expulsive respiratory effort tends to force the abscess walls together. When an abscess is opened and is found to connect with a part of the bronchial tree, it is best to maintain the bronchial fistula for a long time. Operative dangers not detailed are: hemorrhage from erosion of vessels and cerebral air embolism. This is probably the cause of what is called pleural shock. Postoperative rest is of great value.

Dr. John D. Kernan, New York: Bronchoscopy should be done at least once in every case of lung abscess on account of the possibility of the presence of a foreign body, and because of the possibility of a cure after one bronchoscopy. No matter how unfavorable the case appears for bronchoscopy, it is sometimes possible to get astounding results.

Bronchopulmonary Spirochetosis

Dr. David T. Smith, Ray Brook, N. Y.: In the nineteen cases seen at Ray Brook, spirochetes, fusiform bacilli and cocci have been found in every case. Many more cases must be studied, and the organisms must be isolated in pure culture and the disease reproduced in animals before it can be said definitely that they are the etiologic agents. The routine method of treatment in these cases has been rest in bed and postural drainage. During the last year, injections of neoarsphenamine have been given in addition, with improvement in some cases. The success of the treatment depends largely on the duration of the disease. Most of the cures have been obtained in cases of less than six months' standing.

Chronic Pancreatitis

Dr. J. William Hinton, New York: Cases of chronic interstitial pancreatitis are not cured, nor are subsequent attacks prevented, by biliary drainage, as the symptoms are due to a lymphatic infection secondary to a primary abdominal focus, most often a lesion of the gallbladder, and second, an ulcer of the duodenum. The diagnosis should be made in a higher percentage of cases from the history and clinical data without an exploratory laparotomy. The infection seems to be a lymphangitis which spontaneously subsides after removal of the primary abdominal focus.

DISCUSSION

Dr. Charles Gordon Heyd, New York: The statistics furnished by all large clinics on the association of pancreatitis with gallbladder infection would support the assumption that this association does exist. It would appear logical, therefore, to suppose that there must be symptoms produced by a chronic pancreatitis which remain after the original focus of infection has been removed. Most of the cases of residual pancreatitis clear up spontaneously within a reasonable time without the necessity for any further operative intervention.

Dr. Anthony Bassler, New York: The test I devised will show with very little liability of error if a definite condition in the pancreas exists by the simple method of testing the external secretions. We judge our operative cases entirely on the results of this test, and even in chronic cholecystitis we have been able to get a very high percentage of definite stiffening in the pancreas found at operation; and in those cases in which there is a chronic cholecystitis with stiffness there is no question that the gallbladder should be removed. The method is also helpful in operative cases which come back with symptoms to draw attention to the involvement of the pancreas and the relief of those symptoms by various methods of pancreatic feeding.

(To be continued)

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in America for a period of three days. No foreign journals are available prior to 1921, nor domestic prior to 1923. Periodicals published by the American Medical Association are not available for lending, but may be supplied on order. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested).

Titles marked with an asterisk (*) are abstracted below.

American Journal of Medical Sciences, Philadelphia

171: 157-312 (Feb.) 1926

*Vascular Changes in Cases of Polycythemia Vera. G. E. Brown and H. Z. Giffin, Rochester, Minn.—p. 157.
Experimental Coronary Embolism. W. W. Hamburger, W. S. Priest and R. B. Bettman, Chicago.—p. 168.

Pressure Changes in Biliary Tract. J. C. Potter and F. C. Mann, Rochester, Minn.—p. 202.
*Substernal Thyroid. D. Felberbaum and B. Finesilver, New York.—p. 217.
*Prognosis in Exophthalmic Goiter. J. M. Read, San Francisco.—p. 227.
*Total Thyroidectomy in Thyrotoxicosis of Exophthalmic Type. P. K. Gilman and W. E. Kay, San Francisco.—p. 239.
Diagnostic Criteria of Chronic Parathyroid Insufficiency: Phosphate Content of Blood. L. Berman, New York.—p. 245.
*Primary Carcinoma of Lung. J. S. Grove, Chicago, and S. E. Kramer, Perth Amboy, N. J.—p. 250.

Vascular Changes in Polycythemia Vera.—Fourteen cases of polycythemia vera were studied by Brown and Giffin in relation to the vascular readjustments to the increased volume of the circulating blood. The total volume of the circulating blood and its viscosity were increased in all cases. The capillaries of the nail fold showed engorgement of the venous limb in thirteen cases; of the arterial limb, in four cases. There was complete utilization of all available capillaries of the skin. Engorgement of the retinal veins was present in nine cases. Cardiac enlargement and cardiac disease were noticeably absent. The liver was slightly enlarged in 57 per cent of cases. The spleen was enlarged in every instance, and there was a distinct relationship between the splenic enlargement and the degree of increase in the total volume of the blood. There was no increase of blood pressure in polycythemia vera. The renal function was slightly impaired.

Spontaneous Rupture of Heart.—Nuzum and Hagen have collected 320 instances of heart rupture from the literature and add five cases from their own material, classifying the symptoms according to their incidence and giving particular attention to the etiology and pathology. They assert that this condition most frequently follows obstruction of a coronary artery. Coronary thrombosis invariably results in infarction of that portion of the heart wall supplied by the obstructed vessel. Proper management of such a patient will aid in preventing a rupture of the infarcted area.

Pernicious Anemia and Spinal Cord Degeneration.—At least four of the cases of pernicious anemia reported by Reese and Beigler presented some form of neurologic manifestation. It appears that the loss of vibratory sense is almost invariably the earliest sign of neural changes in pernicious anemia, and not infrequently a diagnosis of the disease and subsequent development of cord changes were predicted in spite of a normal blood picture. Cord changes may precede the characteristic blood picture of pernicious anemia, and in such cases the progress of the disease is more rapid, remissions are less frequent and prognosis more serious. Neurologic manifestations are apparently limited to the cord, particularly involving and causing marked tract degeneration of the spinocerebellar and posterior column tracts.

Substernal Thyroid.—Felberbaum and Finesilver call attention to the frequency of occurrence of substernal thyroid and report seven cases. Any shadow in the upper mediastinum, which shows a distinct line of demarcation, and is separate from the aorta, is usually a retrosternal goiter.

Prognosis in Exophthalmic Goiter.—The mortality rate in Read's series of 100 cases was 11 per cent. Exclusive of four deaths directly due to surgery, the mortality rate was 7.3 per cent, and, further deducting three accidental deaths, it was 4.3 per cent. Thirty-eight per cent of patients seem to be cured and about 21 per cent are sufficiently improved as to be restored to full social and economic usefulness. The remaining 30 per cent, which includes twenty-three of twenty-five patients previously operated on, will be sufferers from the disease or its sequelae the remainder of their lives. The tendency for this disease to become chronic in certain instances is a feature which Read feels had not been stressed sufficiently.

Total Thyroidectomy in Exophthalmic Thyrotoxicosis.—Ten patients form the basis of the preliminary report made by Gilman and Kay. Of these, seven had been under continuous medical supervision, including the usual methods indicated by that term, for from one to eight years. Each of these seven had received numerous roentgen-ray treatments, two patients as many as sixty treatments. The operation consisted in removing the entire thyroid gland, the safety of the parathyroids and recurrent laryngeal nerves being insured by shaving the posterior portion of each lateral lobe as close to the capsule as possible. All but two patients received iodine both before and after operation. The results have been most gratifying. After long periods of complete invalidism the patients have resumed their usual occupations and enjoy good health.

Primary Carcinoma of Lung.—Twenty-four cases of primary carcinoma of the lung are analyzed by Grove and Kramer. The striking increase in the number of tumors of the lung since the influenza epidemic suggests some relation between these two conditions. Pulmonary cancer presents a very varied pathologic picture. Metastases occur early and are very widespread. Histogenesis presents many difficulties, because of the morphologic variations in the cells concerned and the difficulty in obtaining the tumors in the early stages for study. Efforts to classify these tumors as to histogenesis admit great probability of error. However, from authentic studies it appears that origin from bronchial mucosa is most frequent and that origin from alveolar epithelium is very rare. There are no pathognomonic symptoms of tumor of the lung—weakness, cough, expectoration, pain in the chest and dyspnea being most important. The use of the bronchoscope for both diagnosis and treatment is advocated.

American Journal of Syphilis, St. Louis

10: 1-200 (Jan.) 1926

Sudden Death Due to Exacerbation of Latent Syphilitic Myocarditis. A. S. Warthin, Ann Arbor, Mich.—p. 1.
*Bismuth Treatment for Syphilis. I. C. Sutton, Los Angeles.—p. 29.
Generalized Cutaneous Syphilis: Clinical Differentiation. III. Frambesia Tropica and Syphilis. H. Goodman, New York.—p. 64.
*Acute Syphilitic Nephritis: Case. A. J. Hood and F. D. Murphy, Wauwatosa, Wis.—p. 89.
Case of Cerebrospinal Syphilis Treated by Inoculation with Malarial Parasites. E. C. Thrash, Atlanta, Ga.—p. 94.
*Pregnancies as Factor in Prevention of Neurosyphilis. H. C. Solomon, Boston.—p. 96.
Standardization of Wassermann Test. R. Gilbert and V. Langworthy, Albany, N. Y.—p. 101.
Sachs-Georgi Reaction. G. Stuart and K. S. Krikorian, Palestine.—p. 131.
Wassermann Test for Syphilis: Natural Antisheep Amboceptor in Human Serum. O. Ishii, New York.—p. 143.
Comparison of Fixation at 37 C. and 36 C. with Cholesterinized Antigen. R. Gilbert, V. Langworthy and A. C. Moore, Albany, N. Y.—p. 162.

Bismuth Treatment of Syphilis.—Sutton concludes that bismuth has not dethroned arsenic, which still holds first place because of its powerful action on spirochetes, but it is particularly indicated in cases of intolerance to the arsenical preparations and in those who may be said to be arsenic fast. It constitutes, therefore, "a great progress in the treatment of syphilis."

Acute Syphilitic Nephritis.—The case reported by Hood and Murphy appears to be one of true syphilitic nephritis, because it occurred during the secondary stage of untreated syphilis, and no other known cause for the nephritis could be found.

Pregnancy as Factor in Prevention of Syphilis.—The history of pregnancy in 559 syphilitic women, 30 years of age or older, was studied by Solomon. About 44 per cent of the women with paretic and tabetic neurosyphilis were nullipara in comparison with 26.5 per cent of nullipara among the women who had syphilis but no evidence of nervous system involvement. Pregnancies were considerably more frequent among the nonnervous system syphilitic patients than among the neurosyphilitic patients. Solomon says that one might draw either of two conclusions: first, that women who develop neurosyphilis become less fertile than women infected with syphilis but without central nervous system involvement, either because the former have a more severe type of infection or because they are infected with a different type of organism, namely, a neurotropic strain which tends to affect the childbearing potentialities of the individual; or, second, that women who become pregnant receive thereby a protection against the spirochete and its attack on the nervous system.

Meningioma.—Two cases are reported by Towne. In one, the superior longitudinal sinus was occluded In the second, a meningioma had invaded the inferior longitudinal sinus and grown extensively in the venous system, terminating in the superior vena cava. The tumor had secondarily invaded and broken through the venous walls in many places.

Giant Cell Tumor of Phalanges.—Two cases of benign giant cell tumor of the phalanx are reported by Cole. The first of these involved the proximal phalanx of a toe, and was cured five and one-half years after amputation The second involved the proximal phalanx of the thumb. This patient was well sixteen months after the phalanx was resected and replaced by a bone graft from the tibia, driven into the metacarpal head. The result is a stiff, but very serviceable, thumb.

Carcinoma of Colon.—In ten years, 257 patients with carcinoma of the right segment of the colon were advised to undergo operation at the Mayo Clinic. Of these, 141 are known to be dead, a few of which, however, did not die from carcinoma. Thirty-four patients were not traced Fifty-five patients lived from one to four years; twenty-five lived from six to eight years; twelve are alive from eight to nine years after operation.

Colonic Polyposis.—Coffey reports one case of colonic polyposis with engrafted malignancy and describes a technic for removing the entire colon including the rectum.

Hemostasis in Suprapubic Prostatectomy.—In Hunt's experience, the Pilcher bag offers a most effective method of hemostasis after suprapubic prostatectomy.

Primary Pneumococcus Peritonitis.—Three cases of primary pneumococcus peritonitis are reported by Leonardo, in none of which was infection by way of the genitalia possible. In one of these cases trauma was a possible etiologic factor.

Relation of Protein Foods to Hypertension.—The results of this study by Donaldson support the suggestion that hypertension may have its beginnings in a type of dietary that produces such a degree of endocrine stimulation as to develop an irritable vasomotor system with its resulting transitory, then permanent, alteration in blood pressure.

Orange Juice as Accessory Food.—Melvin believes that the regular administration of orange juice with children's meals is an important factor in their improved health, and promotes gain in weight

Renal Counterbalance.—Hinman says that it is a popular conception that the remaining kidney, if normal, is able immediately to take over the extra burden occasioned by removal of its mate On closer consideration this is found to be only partially true, and renal reserve is seen to be largely potential and to have an anatomic and functional correlation Studies of structure have shown that growth by hyperplasia or new tissue formation may occur in young animals and man for considerable periods after birth; in human kidneys, up to the fifth or sixth year. Renal atrophy has been almost universally regarded by pathologists as degenerative in type and due to bacterial, chemical or other toxins, producing the well recognized pathologic condition of cloudy swelling, and fatty amyloid and hyaline degeneration But there is also a well recognized type of atrophy which may be termed biologic, due to inanition, pressure or inactivity, and it is possible experimentally to produce what would seem to be an inactivity renal atrophy. For clinical purposes, one may distinguish four groups of renal tissue relative to the adjustments that may follow surgery or disease. Readjustments between these four types of tissue lead to four types of counterbalance The normal renal tissue may show a complete unilateral counterbalance. Readjustments among portions which have an equal qualitative ability to respond instance a cooperative type of counterbalance, whereas readjustments between portions of unequal qualitative ability, irrespective of quantity mass, result in a competitive type of counterbalance.

Acute Rheumatic Fever.—In sixty cases of rheumatic fever reviewed by Heyn, there were eighty-six cardiac complications. Chronic myocarditis and mitral and aortic insufficiency were the most frequent complications, occurring in twenty-three, twenty-one and twenty cases, respectively.

Volvulus of Fallopian Tube.—Gabe reports a case of volvulus of the fallopian tube occurring in a girl, aged 15. The abdomen was opened under a diagnosis of acute appendicitis. There did not appear to be any preceding pathologic change. Gabe says that a preoperative diagnosis of this condition has never been made in reported cases.

*Effect of Iodine by Mouth on Reaction to Intravenous Injections of Thyroxin. C. C. Sturgis, S. Zubiran, G. W. Wells and T. Badger, Boston.—p. 289.

Factors Concerning Acidosis in Chronic Nephritis.—Bulger and his associates are of the opinion that a reduction of total base and an increase of undetermined acids are the most significant factors causing acidosis in chronic interstitial and arteriosclerotic nephritis, phosphate playing a somewhat less important rôle. The degree of acidosis appears to be greatly influenced by variations of plasma chloride. Frequently, especially in the presence of vomiting, chloride may be quite low, thus freeing the base to combine with bicarbonate and resulting in only a slight reduction of carbon dioxide. With high chloride, bicarbonate may be extremely low. These studies emphasize the profound changes which occur in the blood electrolytes in the terminal stages of chronic nephritis.

Nervous Control in Heart Block.—Evidence is presented by De Graff and Weiss to show that in complete heart block the accelerator nerves exert a considerable control over the ventricles, whereas the vagi have only a slight influence. Vagal control over the auricles is the same in complete heart block as in the normal heart. Exercise in complete heart block tends to increase the auricular rate but leaves the ventricular rate unchanged. Cheyne-Stokes breathing in complete heart block may be associated with varying auricular and ventricular responses. A case is reported in which the injection of epinephrine caused a complete change in direction of the ventricular complexes.

Rhythm in Urinary Acidity.—The observations made by Muschat suggest a rhythm in urinary acidity characteristic for the individual and persisting in spite of marked variations in the individual's regimen.

Ammonia and Acid Excretion in Nephritis.—In those forms of nephritis (nephrosis and benign nephrosclerosis) in which the urea excreting function is quantitatively unimpaired, Van Slyke et al. found that both ammonia and titratable acid are excreted in normal amount and proportion. In acute glomerulonephritis a tendency to low ammonia-acid ratios was present in some cases, and absent in others. In those forms of nephritis with quantitatively impaired urea concentrating function (chronic glomerulonephritis and some cases of acute glomerulonephritis), there was regularly a low ammonia-acid ratio. The drop in the ammonia-acid ratio was not always proportional to the fall in urea excreting power nor to the severity of the clinical condition. The ammonia content of the blood was as low or lower in those forms of nephritis with diminished ammonia output as in normal individuals. The concurrence of diminished ammonia formation with diminished kidney function is compatible with the conclusion of Nash and Benedict that ammonia is formed in the kidney. The fall in the ratio, however, although present in all cases thus far observed with impaired urea concentrating power, does not regularly parallel the fall in the urea concentrating or excreting power. The decrease in urea function is more closely correlated with the clinical severity of the nephritis.

Effect of Iodine on Thyroxin.—Sturgis et al. assert that the intravenous injection of thyroxin in rabbits produces a characteristic increase in the pulse rate, basal metabolism and decrease in the body weight. The administration of compound solution of potassium iodide has no effect in altering the characteristic response in rabbits to injections of thyroxin.

Chemistry of Intestinal Flora of Nurslings.—The nitrogenous metabolism of the mixed intestinal flora of twelve nurslings was investigated by Kendall, Day and Walker. The nitrogenous changes induced by the microbes were relatively little. Proteolysis of bacterial origin was minimal. The striking change induced by the mixed flora was a pronounced fermentation of utilizable carbohydrates, particularly glucose and lactose. In these mediums, there was a rapid and intense formation of acid, with almost no indication of nitrogenous changes in the constituents of the medium other than those ultimately associated with the anabolic phase of bacterial activity. This pronounced fermentation (principally lactic) is characteristic of the chemical findings of the combined fecal bacteria of nurslings.

Chemistry of Intestinal Flora of Artificially Fed Infants.—Kendall, Day and Walker found that the intestinal floras of artificially fed children induce putrefactive changes in sugar-free mediums, and fermentative changes in the same mediums to which carbohydrates have been added.

Chemistry of Intestinal Flora of Normal Adults.—The general result obtained by Kendall, Day and Walker from the metabolic study of fairly representative intestinal floras from normal adults is a chemical picture of moderate proteolysis in mediums containing no utilizable carbohydrate, and a supression of this proteolysis nearly to the vanishing point when utilizable carbohydrates are added. One of the potentially useful facts gleaned from these observations is the striking effect of diet on the nitrogenous metabolism of these normal adult bacteria: utilizable carbohydrate, as long as it is continuously available, reduces or suppresses aromatic putrefactive products practically to the vanishing point. Another feature is the low proteolytic change in plain broth cultures, which contrasts strikingly with the marked proteolysis present in those persons whose intestinal flora contains a very easily appreciable overgrowth of gas bacilli, notably *B. aerogenes-capsulatus.*

*Psychogenesis of Confirmed Stammerers. L. P. Clark, New York—p. 238.

Basal Metabolism in Postencephalitic Syndromes.—Forty-seven cases presenting postencephalitic syndromes of different duration and intensity are analyzed by Naccarati. From his findings he assumes that basal metabolism is altered in postencephalitic syndromes and, considering the seat of the destructive lesions which take place in encephalitis, the alteration of the metabolic rate can be connected with changes occurring in the vegetative centers located in the gray substance which surrounds the third ventricle and the aqueduct of Sylvius. Metabolic functions are located in very complicated organs, pathways and centers, which form a chain going from the internal organs, endocrine glands, through the sympathetic nervous system to the vegetative centers of the mesencephalon and basal ganglions. A lesion in any of the structures along this chain will lead to alteration of the metabolic activities.

Psychogenesis of Confirmed Stammerers.—The suggestion is advanced by Clark that all stammerers are oral erotics, but as this form of infantile fixation is really only a part of the character distortion from the three great sources of its formation, i. e., the oral, the anal and the urinary erotism, the oral character formation is always interwoven with other reaction formations, against the primacy of the instinctive impulses to nurse, to soil and to void. This fact accounts for the clinical variations in stammering as well as the varieties of make-up. The main accent must be placed on the varieties of oral erotic behaviors.

Tuberculosis and Pregnancy. J. C. Litzenberg, Minneapolis.—p. 129.
Tuberculosis of Oral Cavity. C. W. Waldron, Minneapolis.—p. 131.

Significance of Pleurisy.—Of 1,182 patients with tuberculosis whose histories were reviewed by Hastings, a history of fibrinous pleurisy and pleurisy with effusion occurred in 55.7 per cent of cases. Hastings feels that this means that fibrinous pleurisy may be the first symptom of pulmonary tuberculosis; hence, patients with fibrinous pleurisy should be warned that they may have tuberculosis.

Flocculation Test in Tuberculosis.—Hardesty prefers the Baum technic. He has carried out the reaction in 300 cases, comprising patients and employees of a sanatorium, and guinea-pigs, healthy and diseased. Strongly positive reactions have occurred only in tuberculosis. The intensity of the reaction is roughly proportional to the extent and activity of the process. Weak positive reactions are occasionally found in those with mild tuberculous infection and in individuals presumably healthy. Negative reactions occurred only once in active tuberculosis. Thus, it would seem that one great value of the reaction consists in its power to differentiate between active tuberculosis in which the bacilli are not found, and other diseases which clinically simulate it.

Diet in Tuberculosis.—Myers urges that the diet of the tuberculous patient must be prescribed by the physician just as drugs are prescribed in certain other diseases. He objects to forced feeding and stresses the importance of meeting the vitamin requirement of the body.

Thoracoplasty in Tuberculous.—Law has done fifty-eight operations on thirty-one patients and has lost only one directly from the operation. This was a one stage operation, and the man died of shock. In all cases he has used local nerve block with procaine, supplemented by nitrous-oxide gas and oxygen analgesia.

Importance of Ear, Nose and Throat Diseases in Industrial Efficiency. I. D. Kelly, Jr., St. Louis.—p. 106.

Warts of Mouth.—Of the two cases reported by Davis, one was a single verruca of the tongue. The other patient had an enormous number of verrucae in the mouth.

Cause of Blindness in Youth.—Of 507 cases of blindness examined by Lamb, 216, or 21.2 per cent, were due to ophthalmia neonatorum, and 154, or 15.1 per cent, to optic atrophy. Only eighty-seven cases were caused by congenital cataract, and sixty-eight each by corneal ulceration and uveitis. Trauma caused sixty-six cases.

Diarrhea in Children.—Zahorsky records some peculiarities of the diarrheal diseases in children during the summer of 1925 in St. Louis. To this is added a summary of the therapeutic procedures employed and a discussion of the modern theories of [illegible] enteric intoxication in the light of this clinical experience. Zahorsky thinks we must go back to intestinal antiseptics, laxatives and specific serums Babies should be immunized when young against colon bacilli by suitable vaccines

Brain Tumors G Horrax Boston —p 186
Value of Blood Chemistry Studies to Surgeon A M Dickinson, Albany —p 190

Treatment of Cardiac Emergencies.—Three points are stressed by Pardee First epinephrine must be used with caution in the presence of a weak pulse due to cardiac failure Second, if digitalis is to be given for cardiac emergencies, it must be given intravenously and in much larger doses than is customary, or the full benefit that digitalis is able to give will not be obtained until the time of the emergency is past Third, these doses should not be used intravenously unless it is certain that the patient has not been taking digitalis within the two weeks preceding

Fertility and Health—The degree of fertility, Macomber says, is indicative of the completeness and normality with which the reproductive organs are functioning It is intimately bound up with conditions of general health and with certain phases of the physiology of the reproductive organs Several abnormal conditions of the body as a whole—namely, anomalies of nutrition, anemia, postural defects, foci of infection and endocrine disturbances—are found frequently associated with lowered fertility Furthermore, these cases of lowered fertility all show some evidence of alteration of function The three forms of alteration most commonly found are hyposecretion, hypersecretion and ovarian dysfunction

Blood Pressure in Women—The records from 1,230 women have been analyzed by Alvarez, and the average blood pressures have been calculated for women of different ages The sexually abnormal averaged considerably higher than the sexually normal Single women were found to average a little higher than the married A masculine distribution of body hair, sexual anesthesia, fibroids of the uterus, thyroid disease, and pelvic conditions requiring ovariectomy or hysterectomy were found to be associated with high blood pressure The evidence presented supports the theory that the essential type of hypertension is a bodily peculiarity inherited equally by girls and boys, but ordinarily repressed in the girls by the ovarian or other related secretions In men, and in women with defective pelvic organs, the disease generally makes its appearance shortly after puberty

Cancer of Cervix Uteri—Of 203 patients that were operated on and in whom the ultimate result is known, thirty-eight (18 7 per cent) are living and well today Of the cases in which the spinal cell is the predominant type of cancer cell, 78 8 per cent of the patients are living and well In the transitional group, 15 1 per cent are living and well, while in the fat spindle cell group the percentage is 4 76 The adenocarcinomas, while showing the smallest percentage incidence of all the cervical cancers, give a 21 4 percentage of apparent cures Martzloff feels that the findings are strongly indicative that the histologic character of the predominant type of cancer cell in cervical epidermoid carcinoma is a good index as to the relative malignancy of the neoplastic process

Remote Results of Focal Infections.—Marriott emphasizes the fact that general and remote symptoms of infection in the ear, nose and throat of children are more important than the local signs, and the examination of the child is not complete unless these infections are sought for.

Pulmonary Streptothricosis.—A case of streptothrix infection of the lung that has been studied by clinical, roentgenologic and bacteriologic methods is presented by Giddings. The organism grew readily on all mediums. It was pathogenic for guinea-pigs, but not for rabbits.

Unwarranted Surgery in Gastric Achylia.—Reviewing the histories of 175 cases of true achylia, Fontaine has been impressed by the fact that in fully 25 per cent abdominal pain has been the symptom for which the patients sought relief. These cases were not associated with pernicious anemia, syphilis, or cancer of the stomach. In many of the instances, the pain, though less severe, has resembled that of gallbladder disease, appendicitis, or peptic ulcer. Fontaine warns against unwarranted surgery in these cases. They are amenable to treatment by the use of liberal doses of hydrochloric acid, with the proper dietetic regimen.

Diet in Prevention and Treatment of Pellagra.—Faust-Newton says that in the treatment of pellagra the ample ingestion of food containing vitamin B and possibly the unknown pellagra vitamin is essential (fresh meat, orange and lemon juice, tomato juice, yeast). The administration of dried brewers' yeast, in sufficient quantities, is so effective that this may almost be termed a specific for pellagra.

Sodoku; Rat Bite Fever.—Lanford advocates the use of the term sodoku for the designation of cases of real rat-bite fever in order to clarify a greatly muddled situation.

Erythema Multiforme Complicating Vaccination.—Fourteen cases of erythema multiforme complicating vaccination are recorded by Eichenlaub, seven of which were seen personally by the author. Definite conclusions as to the causative agent could not be made. The possible analogy between these eruptions and hemorrhagic smallpox is pointed out. The probable incidence of this type of eruption is estimated at approximately one in 10.000 vaccinations.

Headache and Mental Disease.—A complaint of headache in a patient presenting mental disease, Dickerson says, should always be investigated by both fundoscopic and radiographic examinations; a search for organic disease in these patients should be undertaken in all of its details.

Frequency of Symptoms of Peptic Ulcer.—Twenty-one cases of duodenal ulcer and nine of gastric ulcer were analyzed by Cassidy with reference to frequency of symptoms. Epigastric pain was present in every case; hematemesis in eight; gas in nineteen; constipation in sixteen; headache in sixteen, and dizzy spells in twelve cases.

Cardiovascular Diseases in Veterans' Bureau Hospitals.—A study was made of the incidence of heart disease in the Veterans' Bureau hospitals, and it was found that of a total patient load of 26,689 there were 537 who had some form of cardiac disability, an incidence of 2.01 per cent. Of the 537 cardiac cases, 273 were hospitalized primarily for the heart condition, 176 were hospitalized for some major disability to which the heart condition was secondary, and eighty-eight patients had a heart disability which was considered of minor importance. The incidence of heart disease in the colored race is much higher than it is in the white race. A study of the cardiac diseases found in the tuberculosis hospitals show that 191 of a patient load of 9,299 had some cardiac disability, thus making an incidence of 2 per cent. Forty-five of these patients had mitral insufficiency; twelve had mitral stenosis, and fifty had either acute or chronic myocarditis. It is interesting to note that 35 per cent of the heart disabilities are found in patients suffering from pulmonary tuberculosis. This shows that tuberculosis coexists quite frequently with heart disease. The incidence of heart disease in neuropsychiatric patients is very low. Of 12,297 beneficiaries under treatment in neuropsychiatric hospitals, eighty-two had some cardiac disability, an incidence of 0.6 per cent. It is also found that in general hospitals, out of 5,093 patients, 264 were under treatment for heart disease, an incidence of 5 per cent. Of these patients, fifty-eight had mitral insufficiency, forty-nine had acute or chronic myocarditis, twenty had combined mitral and aortic lesions, nineteen were cases of mitral stenosis, and sixty-five patients had heart lesions which were not classified. The most common cardiac diseases observed in Veterans' Bureau beneficiaries are mitral insufficiency, acute and chronic myocarditis, cardiac hypertrophy and mitral stenosis. The high incidence of acute and chronic myocarditis is due to the large number of cases of tuberculosis under treatment, which condition may be an etiologic factor in inflammatory processes of heart muscle.

Stricture of Ureter.—Fifty-five cases are analyzed by Andrews. Forty operations were done on twenty-seven of these patients, and while it is not believed that all these operations were useless, the fact remains that the pain for which the operations were done was not relieved.

Ureteral Stricture.—Martin endeavors to construct a clinical picture of ureteral stricture that may be of assistance to the general practitioner in recognizing this condition. The material consists of twenty cases. Cystoscopic examination showed a well defined stricture of the right ureter. Certain symptoms stand out prominently, especially pain in the back radiating to the bladder, associated with history of bladder irritation at some time, together with localized tenderness. The association of these symptoms alone is sufficient to arouse suspicion of ureteral stricture. While the condition is not extremely frequent, it occurs often enough to make it important that every one should be familiar with the symptomatology. Martin says that in consideration of lower right quadrant pain it is of especial significance, and before a laparotomy is undertaken for the relief of undetermined trouble, stricture of the ureter should be excluded.

Ova in Gall Tract Drainage—Preston reports the case of a woman whose principal complaints had been nausea, giddiness, constipation cramps and paresthesias in the lower extremities and attacks of pain in the hepatic and right renal regions The woman had been subjected to a number of operations without getting any relief On making duodenal drainage, Preston discovered ova in the bile He concludes that there was a female *Ascaris* in the biliary tract most likely inside of the liver This parasite had existed there five or more years judging from a long continued eosinophilia It had been depositing ova for more than a year

Diet and Disease—Mellanby presents what he regards as evidence that defects of diet of women during pregnancy and lactation are responsible for some, and possibly much, of the illness and mortality of young infants The new teachings of diet have been applied to some extent to the feeding of children, and this is no doubt partly responsible for the decrease in infant mortality during recent years at a time when overcrowding and some other hygienic defects are as bad as or even worse than ever, but it is necessary to extend the teaching to the problem of maternal feeding This would probably show its first effect by reducing the infant mortality of children under 1 month of age and would result in great improvement in the physique of children It would increase the resistance of infants to infections which produce catarrhal conditions of the respiratory and alimentary tracts and all the other sequelae so generally recognized as likely to follow It would certainly result in a better grown and less rickety type of child, and would do something also to improve the structure of the teeth and thereby to reduce the appalling amount of caries in the teeth of children It would probably also bring about improvement in the general health of the pregnant woman and do away with some of the unfortunate experiences to which she is liable

Irradiated Cholesterol in Rickets—A case of severe rickets is described by Parsons which had been under treatment during the greater part of 1925 From April to the beginning of September, the child received cod liver oil as an outpatient, but with only slight improvement during the last three months of the year he was admitted into the hospital, and irradiated cholesterol was administered, with the result that the rickets was cured

Etiology of Gastric and Duodenal Ulcer.—In Monsarrat s opinion there is no satisfactory evidence that chronic gastric and duodenal ulceration is primarily due to direct invasion of the stomach or duodenal wall by specific organisms Chronic gastric and duodenal ulceration is not caused by alterations in the chemistry of the gastric secretions The evidence available points to alteration in gastric rhythm being the primary morbid condition which, when persistent, leads to the development of ulceration The site of the ulceration is the site of maximum wear and tear by gastric contents, whose normal neutralization has been interfered with by the altered gastric rhythm The gastric secretions, innocuous to the stomach wall under normal conditions, cause irritation and eventual ulceration, when the gastric rhythm is altered trophic changes may also prepare the way for this action The fundamental condition on which these morbid changes in the gastric motility and rhythm depend is doubtless a disorder of gastric innervation which may have its origin in toxic influences, or psychic influences, or in reflex influences from disease elsewhere The innervation of the stomach is not however so completely analyzed as to make it possible to say whether these influences bear on an autonomic gastric system or whether they affect the stomach by way of the vagus or sympathetic There is, however, some evidence that in the gastric type which is usually associated with duodenal ulceration there is some inhibition of impulses by the splanchnic path and that in the gastric type which is usually associated with gastric ulceration, it is the vagus impulse that is depressed

Perforated Jejunal Ulcer—In a case of perforated duodenal ulcer reported by Ashcroft, a posterior gastro enterostomy was performed and the man made an uninterrupted recovery A year later the patient was readmitted He stated that there had been total absence of pain in the abdomen for seven months after operation At the end of this period he began to experience periodic attacks of generalized abdominal pain, occurring every three days and lasting from ten to fifteen minutes the pain had no relation to food Gradually the characteristics of the pain altered, it became localized to a point 1 inch below the umbilicus and began to show a definite relationship to food coming on about four hours after a meal and lasting until another meal was taken The pain was relieved by self inducing vomiting At the operation a perforated jejunal ulcer was found on the posterior wall of the efferent loop of the gastro-enterostomy coil of jejunum about 1½ inches from the patent gastro enterostomy stoma The ulcer was enclosed by a purse-string suture As the pylorus was found patent, admitting a thumb easily, an entero enterostomy between the afferent and efferent loops of the gastro enterostomy loop of jejunum was performed Three months later the patient was again admitted with symptoms similar to those which followed his first operation A laparotomy was performed, and a second jejunal ulcer was discovered in close proximity to the gastro-enterostomy stoma A partial gastrectomy, which involved three fourths of the stomach and the whole of the loop of the jejunum taking part in the gastro-enterostomy, was performed The man made an absolute recovery In a second case a posterior gastro enterostomy was performed for a juxtapyloric ulcer The patient was again admitted three months later with signs suggestive of a perforated duodenal ulcer The abdomen was opened and a perforated jejunal ulcer was found on the efferent loop of the gastro-enterostomy coil of jejunum

Treatment of Septic Tuberculous Arthritis—O'Conor opens all sinuses freely so as to expose the interior (and recesses) of the joint Every visible particle of diseased bone and tissue is removed, and copious irrigation with warm hydrogen peroxide (1 17) and phenol (1 70) is done Then large wisps of silkworm gut are introduced, and the rest of the cavity is packed with rolls of gauze wrung out of freshly prepared iodoform emulsion The flushing and packing is repeated after forty-eight hours The patient is kept outdoors the part being maintained in absolute rest

*Some Statistical Aspects of Tuberculous Meningitis. J. L. Halliday.—p. 160.

Virulence of Tuberculous Viruses.—Of sixty-three viruses isolated by Munro and Cumming from "surgical" lesions, twenty were found to be of the bovine type, two of these being, however, somewhat less virulent than typical dysgonic viruses, one of which was atypical in both culture and virulence. Bovine bacilli are very rarely obtained from pulmonary lesions, but they are frequently obtained from glandular lesions. By selection according to age groups and lesions, one can show a distinct age and tissue incidence of bovine infection.

Reaction Curves of Tubercle Bacillus Strains.—Cumming says that the amount of information derived from a study of the reaction curve in the differentiation of human from bovine strains of tubercle bacilli is not commensurate with the amount of time and labor involved.

Diagnosis of Pulmonary Tuberculosis in Children.—If there is no generalization of the disease throughout the lung, and the enlarged spleen, enlarged glands, and the presence of papuloneurotic tuberculids do not come to aid, Findlay says, the physician may not even surmise that he is dealing with tuberculosis, whereas the radiologist may, with the utmost confidence, diagnose the true nature of the disease.

Statistics on Tuberculous Meningitis.—Halliday's statistics show that the yearly death rate from tuberculous meningitis bears a more or less constant ratio to the yearly death rate from all forms of tuberculosis; in other words, tuberculous meningitis has declined at the same rate as tuberculosis in general. Tuberculous meningitis had a maximum seasonal prevalence in spring and early summer. This appears to be a belated manifestation of the conditions unfavorable to the respiratory system which obtain during the winter months. The spread of tuberculous infection, like that of diphtheria and scarlet fever, does not appear to be influenced by overcrowding and bad housing conditions, as tuberculous meningitis is no more common in the child population of the smaller houses than it is among children in the larger houses.

Isolating and Cultivating Vibrios from Feces.—Using bowls and tank mud, Tomb and Maitra imitated Nature and manufactured artificial ground tanks for the purpose of using them as a culture medium for vibrios. To 250 cc. of sterilized tank water, 1 per cent common salt and 0.1 cc. of a 1 per cent sterile peptone solution are added before inoculating the medium with feces. This method of isolating vibrios from feces and cholera stools has proved a great advance over all other existing methods, not only on account of its greatly increased accuracy but also on account of its cheapness.

Katakar Oil Poisoning.—Katakar oil is obtained from the mustard-like seeds of an Ayurvedic medical herb known as Sialkata. The scientific name of the plant is *Argemone mexicana* Linn., an American weed commonly known as the Mexican prickly poppy. The use of mustard oil adulterated with katakar oil causes symptoms like those of epidemic dropsy.

Iodine Intravenously in Bubonic Plague.—Bharadwaj reports good results from the use of iodine intravenously in the treatment of plague. He uses a solution of 18 grains ($1\frac{1}{6}$ Gm.) of iodine in 4 ounces (120 cc.) of physiologic sodium chloride solution and injects from 5 to 10 cc. in one dose every day for four consecutive days. Early cases are very easily controlled, and from three to five injections are sufficient to effect a cure. The iodine treatment gives better results if it is supplemented with injections of pure phenol into the bubo, or of $\frac{1}{16}$ grain (4 mg.) of mercuric chloride in 2 cc. of distilled water into the lymphatic area drained by the group of glands in which the bubo has formed. No mercurial poisoning resulted from as many as three such injections given consecutively. No nourishment except water should be given for three days, and a mixture containing potassium iodide and stimulants should be given every four hours.

Hemorrhage in Pons After Tonsillectomy.—Tawse records the case of a child who died suddenly twenty-three hours after removal of tonsils and adenoids. There was no cause of death apparent. The necropsy disclosed a hemorrhage, the size of a large peanut, in the center of the pons.

Retained Tooth Root Is Sneezed Out.—Ormerod reports the case of a woman, aged 21, who had a right upper premolar tooth extracted, one root being broken and retained. Six months later the patient was wakened in the morning by a tickling feeling at the back of the nose. A violent attack of sneezing resulted in the expulsion from the left nostril of the root of the bicuspid. Transillumination and puncture showed the right antrum to be full of a thin purulent fluid. The roentgenogram showed a large cavity in the region of the upper bicuspids with a very irregular and thin layer of bone separating it from the antrum. Ormerod concludes that the dental root must have become loose in an abscess formed around it; the tooth then passed into the antrum through an erosion in its floor and escaped through the normal ostium into the nose, from which it passed back into the nasopharynx and was then sneezed out.

Prevention of Tuberculosis. S. L. Cummins.—p. 169.

Disease Carrier Problem.—Ledingham says persuasion and instruction will do more to reduce infection from declared carriers than any compulsory order rigidly applied. At the same time the community for its own security must have full power to retain on a permanent register all declared carriers, to insist on notification of all changes of address, to examine at any time their discharges and if necessary to remove to hospital for this purpose.

Prevention of Rheumatic Disease.—Ray asserts that nearly one sixth of the total invalidity of Great Britain is directly due to diseases classed as "rheumatic." Each year these diseases alone cost the Approved Societies nearly 2,000,000 pounds in sickness allowances and nearly 3,000,000 weeks are being lost to the nation in consequence. The importance of a publicity campaign with the object of educating the public in the need for a concerted effort to protect children from the devastating effects of this disease is strongly urged by Ray. Special hospitals for the treatment of children who have had an attack of rheumatic fever should be established all over the country. These institutions would differ from the ordinary hospital in that the patients would be kept for prolonged periods. The most satisfactory treatment is said to be "hydrological," implying the use of waters, baths and physical methods generally.

Unusual Case of Pneumothorax. B. Morgan.—p. 656.

Dietetic Treatment of Diabetes Mellitus.—The diet scale used by Percival is that described by Murray Lyon, consisting of three types graded according to the carbohydrate-fatty-acid ratio. The various diets are selected and interchanged to suit the requirements of individual cases during varying degrees of tolerance. Insulin is withheld, except in cases possessing such a low carbohydrate tolerance that it is impossible to abolish glycosuria, or to continue an adequate caloric intake by dietary measures alone. When required, insulin is injected two hours before a meal, except in very severe cases, when the interval is reduced at first to one or one and a half hours. The beneficial effect of this line of treatment is forcibly illustrated by those cases in which large doses of insulin have been diminished and ultimately stopped, while the patient has continued to take a generous diet, the constitution of which presents no extreme variation from the normal. In some of the cases treated by diet alone, a sugar tolerance approaching almost normal has been reached, and the injury to the pancreas has been apparently either recovered from or compensated for. On the other hand, in those who required insulin, the tolerance regained is not nearly so great. The cases reported by Percival are said to emphasize, first, the controllable character of the disease in the majority of cases treated on physiologic lines with the whole-hearted cooperation of the patient, and secondly, the fact that a surprising adequate carbohydrate tolerance may be recovered.

Ventricular Rate in Stokes-Adams Disease.—A continuous electrocardiogram of the whole of a Stokes-Adams attack is reproduced by Herapath. It suggests an explanation of the attacks of ventricular asystole. The attacks of asystole in a case of complete heart block were abolished by injection of epinephrine.

Incision for Double Herniotomy.—Morrison makes a 1½ inch (4 cm.) transverse incision along the line of the crest of the pubis which gives free access to either external abdominal ring. The incision is deepened till the surface of the aponeurosis is reached. With quite moderate traction the region of the abdominal ring is exposed. An oblique incision through the soft parts parallel to Poupart's ligament brings the cord and its coverings into view. The operation can then be completed in the ordinary way.

Effect of Exercise on Size of Erythrocytes.—A method for investigating the mean size of human erythrocytes before and after exercise is described by Dryerre et al. In this method the cells are measured without having been exposed to any atmosphere other than one such as would be in equilibrium with the gaseous content of the blood vessel from which they were withdrawn. By this method, no difference has been found between the mean diameter of the cells before and after violent exercise.

Syphilis in the Working Classes.—Jeanselme and Burnier compare the statistics of new syphilitic infections in France and in other countries the last six years. While the number of recent cases of syphilis has been decreasing in Belgium, Switzerland, Denmark and Austria, it has been increasing among workers in France. This fact seems to be due in part to the afflux of foreigners and natives of French colonies. It is not the imported virus which is accused, since 82 per hundred of the newcomers contracted their syphilis in France. At the St. Louis Hospital, Paris, the new infections formed 50 per cent of the total in 1919; then dropped to 31 per cent in 1923, and climbed to 60 per cent in 1925. Another factor in the increase is the tendency of French physicians to replace arsphenamine by bismuth, which is considered by Jeanselme and Burnier as less effective in treatment of syphilis.

Anatoxin in Mass Vaccination During Diphtheria Epidemic.—Zoeller applied anatoxin vaccination on a large scale in newly enrolled soldiers during an epidemic of diphtheria. A dose of 0.5 cc. of anatoxin was used for the first injection, 1 cc. for the next; the intervals, three weeks and eight days. In 305 with a positive Schick test, diphtheria appeared in 3.6 per cent after one injection; in 2.84 per cent after two, while among the nonvaccinated (including all the older soldiers) the percentage was 3.67. In another group of eighty-eight with a positive Schick test, twenty-eight were injected once or twice, and sixty, three times. Diphtheria occurred in 50 per cent after one or two injections; in 10 per cent after three. Among the controls the percentage was 50 per cent. The membranous throat disease, among the vaccinated, was not accompanied by phenomena of diphtheria intoxication. It disappeared spontaneously, without antitoxin treatment. This may represent an allergic form of diphtheria sore throat. The complete immunity from anatoxin seems to be preceded by a relative immunity—an allergic phase allowing the development of an attenuated diphtheria. No untoward by-effects were encountered in the nearly 3,000 injections of the anatoxin.

Epidemic of Relapsing Fever in Spain. Sadi de Buen.—p. 294.
*Neuromas in Cystic Ovary. G. Roux.—p. 295.

Neuromas Responsible for Pains with Cystic Ovaries.—Roux examined a certain number of ovaries with sclerous and cystic degeneration, accompanied by dysmenorrhea, severe pain in the small pelvis and sometimes even epileptic seizures connected with menstruation. He found numerous neuromas, formed from sympathetic fibers, scattered around the arteries; they may explain the nervous manifestations. The lesions of the ovarian parenchyma were relatively insignificant. Periarterial sympathectomy on the hypogastric or the presacral branch might be considered in these cases, he adds.

*Parathyroid Implant in Tetany. C. Frugoni et al.—p. 355.
Effect of Lumbar Puncture on Diuresis, Glycosuria and Blood Pressure. A. Ravina.—p. 358.

Electrocardiography of Recurring Syncope.—Lian and Petit report cases of recurring syncope without clinical changes of the heart rhythm, or with *only slightly retarded heart beat.* Electrocardiograms revealed block of the right branch of the bundle of His, thus explaining the tendency to syncopes. One of the patients soon died; another developed a lesion of the whole of the bundle of His. In two cases the functional derangement subsided and the improvement has persisted for two and a half years. By adapting itself to the auriculoventricular dissociation, the heart may correct for a long time the tendency to syncopes.

Parathyroid Graft in Tetany of Adult.—Frugoni, Scimone and Comolli report a case of chronic tetany in a young electrician, associated with epilepsy, both cured by transplantation of a parathyroid gland into the vaginalis of the right testicle. The parathyroids were taken from a girl during an operation for goiter. The technic for the grafting was that of Voronoff. Since the operation, made in June, 1925, there have been no manifestations of epilepsy or tetany. The previous low calcium content of the blood returned to normal at the same time as the phenomena of parathyroid insufficiency disappeared. The graft can be palpated now the same as at first.

Is Sciatica a Nerve or Muscle Disease? J. Rouillard.—p. 372.

Extracts of Tubercle Bacilli in External Tuberculosis.—Nègre and Boquet recall that *their "methyl antigen"* is prepared from tubercle bacilli treated previously with acetone. They have used it in 500 cases of different forms of tuberculosis, in a 10 per cent solution, by subcutaneous or intramuscular injection, in gradually increasing doses to 1 cc. Then the undiluted antigen was employed, gradually increasing to 1 cc.; this amount was never surpassed. The injections were given at from two to eight day intervals; sometimes every day. There was no local or general reaction as from tuberculin. Improvement of the general condition occurred after four or five injections. Sixty cases of external tuberculosis are cited proving the local action of the antigen. Remarkable results were noted in lupus and tuberculous processes of the nasal and laryngeal mucosa, and of glands, bones, joints and peritoneum. Improvement of the local lesions was manifest in from three to eleven months.

"Channel Fever."—Bohec's term is "land fever," for the set of symptoms sometimes experienced when, after an ocean voyage, the ship enters a relatively land-locked body of water. The syndrome is similar to seasickness, and is related to certain forms of asthma, etc., the whole forming an anaphylactic colloidoclastic shock in the emotionally predisposed. Desensitization, both psychic and biologic, is required in treatment.

*Asthma in Children. J. González Meneses y Jiménez.—p. 5.
Surgery for Spastic Infantile Paralysis. M. Bastos Ansart.—p. 11. C'td.
*Meningococcus Meningitis in Infant. J. de Cárdenas y Pastor.—p. 50.

Asthma in Children.—González Meneses has found thyroid treatment exceptionally effectual in asthma of the capillary bronchitis type, which is the most common form. The children were between 3 and 8 years old, and some had been having attacks of asthma for years. The treatment was with thyroid tablets, from 0.03 to 0.05 Gm. daily, at one time, kept up for several months. Some of the children have taken them for more than a year, and always without signs of toxic action from these small doses. The brilliant outcome suggests that the asthma was due primarily to thyroid insufficiency. In fourteen cases thus treated, thirteen were completely cured, some of the children having no further attacks from the very first. In the one case in which it failed, the asthma was of the "horse asthma" type. Some time later this child was given an injection of diphtheria antitoxin—as a kind of protein therapy—and the child died in half an hour. Protein therapy should be applied very cautiously to children with asthma.

Meningococcus Meningitis in an Infant.—The special feature of the case was the complete recovery without sequelae under intensive treatment, although it had not been begun until there had been nuchal rigidity for twenty days. Then a total of 120 cc. of the antiserum was injected into the ventricles in six days, and an additional 20 cc. in the three following days, with 60 cc. into the muscles in the first six days. The infant was 6 months old and had been breast fed until the last two months.

Typhoid with Two Relapses. M. Rodella.—p. 1294.

Implant Treatment of Joint Disease.—Robertson Lavalle's method was described in these columns, March 20, page 916. He here brings his record down to date, with nineteen illustrations, confirming the complete cure with his technic which requires *only twenty-five days in bed.* The list includes tuberculous osteo-arthritis and other lesions of the knee, hip joint and elbow.

Alcoholism in Children.—Obarrio insists that wine and beer are always injurious for children, even in very small quantities. The evil effect may be apparent only during sleep or in change of character or in nervous affections—all the pathologic conditions encountered in adult alcoholics may be observed in children. In his own experience, oneiric hallucinations in children were traceable to chronic alcoholism in 98 per cent of the cases. One child of 5 was extremely irritable and had lost the right Achilles tendon reflex and the liver was much enlarged; she had been given wine and beer since early infancy. One boy of 5 had been given wine for a year, and had developed polyneuritis, alcoholic cirrhosis and oneiric hallucinations. Obarrio has encountered three cases of alcoholic polyneuritis in children, one less than 4 years old.

Fever Treatment of Multiple Sclerosis —Dreyfus and Hanau induced fever in treatment of multiple sclerosis patients. They observed some improvement with typhoid vaccine, and gained a decidedly favorable impression with malaria treatment in eleven out of twelve cases

Immunization Against Tuberculosis — Langer injected guinea pigs with his vaccine, consisting of killed young cultures of tubercle bacilli These animals survived an intracutaneous injection of tubercle bacilli on an average about twice as long (six and a half months) as the controls

Reflex in Hyperthyroidism —Serejski observed a local redness and perspiration in the thyroid region after injections of pilocarpine in patients with symptoms of hyperthyroidism. He calls the phenomenon the 'regional vegetative reflex"

Drainage After Laparotomy.—Pohl avoids infection of the main suture by making a small incision to one side and draining through it The method is similar to that of Tschassownikoff

Cerebrospinal Fluid Test.—Bloch and Rosenfeld have devised a new colloidal test for inflammatory changes in the cerebrospinal fluid. They base it on the fact that with p_H of 5 the globulins are positively charged while the albumins have a negative charge. With this actual acidity the latter increase the flocculation of night blue by electrolytes; the former stabilize the colloidal solution. The results of the test corresponded to the premises, flocculation occurring in inflammations of the meninges, while the majority of fluids taken from general paresis patients inhibited flocculation.

Structure and Function of the Capillaries.—Tannenberg examined by direct inspection the capillaries in the pancreas and mesentery of living rabbits and frogs. An active contraction is caused by the adventitia cells in the rabbit; the endothelial cells seem to contribute to it in frogs.

Insulin in Toxicosis of Infants.—Wagner advises in desperate cases of toxicosis in infants to use the method he devised with Priesel. They inject a certain quanity of insulin, and from forty-five minutes to an hour later, give an intravenous injection of 150-300 cc. of a 10 per cent solution of dextrose. One unit of insulin should correspond to 50 cc. of this solution. The immediate effect is excellent, but a relapse occurs within twelve to twenty-four hours unless the condition of the intestine has improved. They had to repeat the treatment in certain infants up to five times.

Testing of Arsphenamine.—As the German patent protecting salvarsan has expired, Kolle has worked out a method for determining the toxicity, and also the curative value of different brands of arsphenamine. Since the resistance of the animals varies, as well as the virulence of the trypanosomes which are used for testing, a standard arsphenamine has been taken for comparison. After this, clinical tests are necessary to avoid the angioneurotic syndrome.

Inoculation with Tuberculin plus Cowpox Virus.—Moro and Keller have made further experiments on the effect of intracutaneous injections of tuberculin plus cowpox lymph. Concentrated glycerol bouillon injected instead of the tuberculin produced the same allergy. A tuberculin free from albumose is less active. Killed lymph is not suitable, but a transitory slight tuberculin allergy was observed after vaccination (without tuberculin). Simultaneous injection of cowpox and old tuberculin on different parts of the body produced the tuberculin allergy.

Parasitic Origin of Cancer.—Blumenthal surveys the recent research on the parasitic origin of cancer and especially the bacillus cultivated by Auler, Meyer and himself from human cancers. They produced cancer in animals by injecting it.

Virus of Smallpox and Herpes.—Heymann quotes Jenner's observations on inhibition of the development of the smallpox vaccine pustule in subjects with herpes or other skin disease entailing serous secretion.

Silent Infection in Weil's Disease.—Reiter produced with attenuated cultures a silent Weil infection in guinea-pigs. The animals for a few weeks resisted reinfection. No silent infection was obtained in trypanosomiasis—probably because this disease does not cause immunity.

Epidemic Angina Pectoris.—Kohn investigated the original reports on the epidemic of angina pectoris on the gunboat *Embuscade* in 1862. Tobacco had often been incriminated, but it is more probable that lead was the cause.

Cyanide Poisoning from Shoe Cleanser.—Ullmann investigated the cause of general malaise and headaches in several girls employed in a shoe store. He found a considerable quantity of cyanide in a fluid shoe cleanser, manufactured by Whittemore Brothers in Boston. A mouse placed in a jar containing 1 cc. of the fluid died within two minutes. He suggests an international prohibition of similar preparations.

"Sanocrysin" Treatment.—Ulrici had good results in superficial lupus with infiltration of the area with 10-15 cc. of a 2-3 per cent solution of "Sanocrysin," with an anesthetic. Tuberculosis of the larynx or mouth was not cured. He considers his results in pulmonary tuberculosis as fair.

Function of the Ovary.—Zondek and Aschheim implanted different pieces of human ovaries in mice in order to determine the points where the ovarian hormone is produced. In the postmenstrual phase, the retrogressing corpus luteum contains no hormone. The wall of the maturing follicle, the follicular fluid and the fully developed corpus luteum contain the hormone. It is present also in the corpus luteum of pregnancy and—during pregnancy—in the atretic follicles rich in theca cells. It is not certain whether the placenta produces or merely stores the hormone. They believe that the theca cells produce it.

The p_H and Disinfection.—Keysser and Ornstein find that the hydrogen ion concentration is perhaps the most important factor in the action of various disinfectants. Bacteria are killed almost instantly when it is optimal. They had excellent results in treatment of peritonitis with such fluids.

Water Metabolism and the Liver.—Lenaz believes that the assumption of a functional occlusion of the veins in the liver is superfluous. He thinks that the regulation of the water content of the blood is a function of the equilibrium between the hydration pressure of the blood colloids and the capillary pressure. If the former decreases (for instance, after drinking) the fluid filters into the pericapillary spaces—including those of the liver. Apart from the primary changes of hydration pressure, hydremia can occur only with a decrease of the capillary pressure. This may be due to weakening of the heart or to dilatation of the capillaries, especially in vagotonic reactions. A lower level of calcium seems to be responsible for it in the paradoxic epinephrine reaction, hydremia, hepatic opsiuria and hemoclastic crisis.

Insulin and Diabetes.—Dietrich, Häusler and Loewi found that human erythrocytes absorb more dextrose from rabbit plasma taken two hours after an injection of insulin than from the normal plasma. Since insulin increases in vitro the absorption of glucose only in the presence of plasma or serum, they conclude that it acts only indirectly in modifying the serum. It seems that the substance which is directly responsible for the increased avidity of erythrocytes, is dialysable. They found also that the serum from diabetic patients or animals with epinephrine glycosuria inhibits the absorption of dextrose by normal erythrocytes. The dialysate of such serums inhibits it also.

Allergy to Tuberculin.—Gröer, Progulski and Redlich confirm the artificial production of tuberculin allergy by injection of a mixture of tuberculin and hog serum: Guinea-pigs sensitized with it reacted with an anaphylactic shock to reinjection of the mixture, but not to hog serum alone, and only slightly to tuberculin. Injection of a mixture of hog serum with cowpox vaccine killed by heat produced a slight tuberculin allergy in children.

Marble Bones Disease (Osteosclerosis Fragilis).—Bernhardt reports a typical case of Albers-Schönberg's disease, with spontaneous fractures, diffuse endostal osteosclerosis, disturbance of growth, suppurations, splenomegaly and enlargement of lymph nodes with myeloid metaplasia. The anemia is secondary—due to the loss of functioning bone tissue. Splenectomy has been suggested, but this is irrational since the spleen is the most important seat of the regeneration of the blood in such patients. Treatment with ammonium chloride did not help much.

Pure Cultures of Spirochetes.—Reiter describes solid and fluid mediums for cultures of spirochetes. They are suitable for preparation of Klopstock's antigens He also mentions therapeutic results of injections of living *Spirochaeta pallida* cultures in general paresis patients after the treatment with therapeutic relapsing fever had failed

The Blanching Phenomenon.—Zlatogoroff and Derkatsch obtained the Schultz-Charlton blanching phenomenon with the serums from animals immunized with the streptococcus toxin or immunized with living virulent cultures of streptococci Killed germs induced formation of agglutinins and complement fixation antibodies, but no blanching properties They conclude that the substances responsible for the Schultz-Charlton phenomenon are formed in response of the organism to the scarlet fever streptococcus. They are not present in the euglobulin fraction of the serum.

Skin and Lymph Nodes in Tuberculosis.—Martenstein and Amster infected guinea-pigs intracutaneously with 0.01 mg. of tubercle bacilli. They observed a local periodic exacerbation, healing and recurrence. The regional lymph nodes showed at the same time an almost opposite curve—swelling with the regression of the cutaneous process and vice versa The smaller the infecting dose, the larger were the lymph nodes in their experiments.

Dextrose and Cancer.—Rondoni found that injections of dextrose had an enhancing action on the development of precancer warts on the tarred ears of rabbits.

Pharmacology of Sulphur.—Burgi and Gordonoff found two or three times as much glycogen in the livers of rabbits fed for a longer period with sulphur as in the controls They point to the sulphur content of insulin found by Abel and Geiling.

Spasmophilia.—Stoeltzner restricts even in latent spasmophilia the daily intake of cow's milk to one half of the previous amount, giving a pint as the maximum In manifest spasmophilia, fasting for a day and a milk-free diet later are indicated. The food, however, must not consist solely of sweetened flour gruels; bouillon, proteins, fat have to be added. A teaspoonful of cod liver oil should be taken twice daily for months. In grave conditions, he prefers to give for a few days twice daily 5 Gm. of the solution: phosphorus, 0.01; oleum jecoris aselli, 100.0 parts. With persisting laryngospasm, large doses of calcium may be necessary: he gives then for five hours every hour 1 Gm. of dry calcium chloride (or 2 Gm of the crystallized), then every three hours another gram, thus administering about 10 Gm. within the first twenty-four hours. After this 1 Gm. of the dry calcium chloride should be given six times daily. The doses should be reduced with clinical improvement, returning to the original large amounts if the spasm reappears.

Hormones and Vitamins.—Wolfer found with Bock's method in the blood from patients with extremely acute psychoses large amounts of anisotropic droplets. He observed similar droplets in various vegetable and animal extracts containing vitamins.

Quinine Rash.—Zacharias' patient had an itching vesicular eruption on the inner side of thighs, the scrotum and the penis. He had had a similar rash on the scalp before, after using a hair tonic containing quinine. This time the eruption was due to the quinine in the contraceptive preparation used just once by his wife.

Pregnancy Ileus.—Luchs draws attention to pyelitis among the causes of ileus in pregnancy.

The Kielland Forceps.—Baumm extols the advantages of the Kielland forceps for the practitioner. He is opposed to Frankel's advice to perform cesarean section if the high forceps fails Even with slight traction, made by a good obstetrician, the forceps may injure the child's brain gravely. Failure of forceps is an indication, he says, for perforation and for nothing else.

Etiology and Prevention of Congenital Dislocation of the Hip Joint.—Krukenberg points out that a paper on this subject would be out of place in a journal devoted to obstetrics, if it were not possible for the obstetrician to prevent the dislocation The anomaly is not to be found in new-born infants. There is only a predisposition in the smallness of the ossification nucleus of the head of the femur, and shallowness of the acetabulum Anteversion of the neck of the femur exaggerates this predisposition The torsion is present in 20-30 per cent of the new-born, in 12 per cent of adults, and does not occur at all in fetuses of 4 months and in quadrupeds. With extension of the femur, its head leaves the anterior margin of the acetabulum in proportion to the degree of anteversion. The simultaneous stretching of the iliopsoas increases the anteversion further. These considerations as well as the frequency of dislocation in children born in breech presentation, led him to attempt to produce a similar condition in dogs. He put three puppies on the fifth day, without undue force, in a plaster cast which kept the hind legs extended for fourteen days The male puppy remained normal, but the two females developed gradually all the signs of "congenital" dislocation of the head of the femur. These experiments confirm the fact that the dangerous stage for dislocation occurs at the time of the extension of the thigh It is therefore essential for its prevention to avoid wrapping up the baby's legs in the extended position and to take care to refrain from trying to teach the child to walk until it changes spontaneously from crawling to the erect position This applies with special force if the child was born in breech presentation, and if dislocation of the hip joint has otherwise occurred in the family. Roentgen examination is necessary with the slightest disturbances in gait, since a beginning dislocation may be cured without operation or plaster cast.

Ovarian Hemorrhage or Pregnancy?—Traugott admits the possibility of grave hemorrhage from the ovary only in leukemia, phosphorus poisoning, extensive burns, hemorrhagic diathesis, hypertension and neoplasms or acute torsion. All the other reported instances were, probably, overlooked extra-uterine (usually tubal) pregnancy. Of such was his case with apparent bleeding from a large ruptured cyst in the ovary in a young unmarried woman. The ovum was found in the abdomen but the tube was macroscopically normal. Sections revealed syncytial cells resembling chorion.

Earth Alkalis. E. Wiechmann.—p. 328.

Action of "Sanocrysin."—Le Blanc tried "Sanocrysin" at Brauer's clinic in the original dosage (0.5-1 Gm.). The toxic reactions were the same in tuberculous and nontuberculous subjects. He does not hesitate to declare that the shock is a manifestation of metal poisoning—not of cleavage products from the tubercle bacilli. He saw no demonstrable specific action of the drug in tuberculosis.

Specific Dynamic Action.—Bahn finds that the intensity of the specific dynamic action of proteins is determined by the tonus of the vegetative nervous system. A certain inverse proportionality between the height of the basal metabolic rate and of the specific dynamic actions was confirmed. He thinks that various hormones change the specific dynamic action indirectly by influencing the basal metabolic rate.

Phenobarbital in Breast Milk.—Frensdorf gave an epileptic woman three times daily 0.1 Gm. of phenobarbital for a few days before and after labor. Her child was normal at birth, but became gradually more and more sleepy. She recuperated after the mother had discontinued the drug.

Treatment of Surgical Infections.—Krecke extols the benefits of Bier's method of treating infections from instruments contaminated with pus. He uses hot dressings and twice daily a local bath of half an hour to an hour's duration in hot chamomile tea. No aluminum subacetate or alcohol dressing should be used. As soon as pus appears (not sooner), surgery is necessary. Several small incisions are preferable to one large. The large tumors of cervical lymph nodes, which are frequent after scarlet fever and measles, often yield to hot applications. A patient with a furuncle of the face—no matter how innocent it looks—should stay in bed. Every occupation—including the mental—as well as all talking and company are prohibited. An ointment should be applied locally and be covered with a small hot chamomile bag. An elastic band, 2 cm. wide is applied to the neck and drawn as tight as the patient can comfortably stand. It should stay on every day from noon till 8 a. m. the next morning. The core must not be expressed, and no superficial incision made. The patient must not get up until the core has been cast off. Local injections of chemotherapeutic preparations are liable to injure the tissues. Many patients with empyema of the pleura, especially in children, recover after simple punctures. An early incision is necessary in a panaritium, acute purulent inflammation of the lower jaw and the deep phlegmon of the neck or forearm. General anesthesia is essential. With a mere paronychia, the phalanx should be smeared thickly with gray ointment and covered with a protecting dressing. Slight pain occurs on the second day, but the finger is healed within eight days.

Action of Roentgen Rays.—Lieber believes that the antagonism between potassium and calcium is closely connected with the Donnan equilibrium. With a special method, he found in sections from skin a large amount of potassium around the hair follicles and in the epidermis. It increases the permeability of the cell wall. Calcium is present in the connective tissue only in a regular network arrangement. After exposure of the skin to a depilatory dose of roentgen rays, the amount of potassium decreases after five days, and the calcium moves toward the epidermis and around the hair follicles. This process progresses until the fourteenth day—when the loss of hair suddenly sets in—the potassium is no longer present in the epidermis, and a layer of cells containing plenty of calcium has practically usurped the place of the original epidermis. Before the beginning of any visible repair, the surroundings of the hair follicles and the regenerating epidermis fill with potassium, and the calcium recedes. He is extending this research to roentgen treatment of tumors.

*Older Primiparas. R. Remmelts.—p. 613.
Prolapse and Constitution K. Burger.—p. 615.
Treatment of Retroflexion. A. Werner.—p. 621.

The Capillaries in the Pregnant.—Pischzek and Schmidt observed pronounced tortuosities both in the afferent and the efferent capillaries of skin in three women with hydramnion. The capillaries changed back to normal after the childbirth. There were other changes in pregnant women with edema.

Rupture of Uterus After Cesarean Section.—Wetterwald points to the lessened danger of rupture of the uterus in a subsequent labor after cervical cesarean section as compared with the classic technic. Placenta praevia increases the danger of rupture.

Older Primiparas.—Remmelts concludes from his material of 103 primiparas over 30 years old that the question of difficult labor in them is merely a question of constitution. Those with hypoplastic sex organs, late menarche, slight menstruation, small fertility, and tendency to abortions, tend to have a prolonged labor.

*Hippocrates in Art. J. B. F. van Gils.—p. 542.
*Medical Topics at International Congress on Goat-Breeding. E. Brouwer.—p. 576.

Fever in Course of Syphilis.—Bottema warns the general practitioner not to be misled by the presence of fever to overlook the possibility of a syphilitic origin for the symptoms presented, although fully 75 per cent of all cases of syphilis run their course without fever. In one of three typical cases described, there was no other manifestation of the syphilis at the time, and the only proof of the nature of the high fever returning every day was its immediate subsidence after a single injection of neo-arsphenamine. In another case the fever accompanied bronchitis, with headache and cough but no expectoration, four or five years after the acquiring of syphilis. There was also a diffuse roseola, similar in every respect to a primary roseola. The symptoms, including the bronchitis, all promptly subsided under treatment with arsenicals. He adds that although the whole of pathology is not included in tuberculosis, syphilis and diatheses, yet these three should always be held in mind.

Roentgen-Ray Diagnosis of Death of the Fetus.—Tengbergen found Spalding's sign (lapping of the skull bones) in ten of eighteen cases of intra-uterine death of the fetus examined with the roentgen rays. The age of the fetus ranged from 26 weeks to term. The heart sounds had been heard up to seventy-two hours before in one case and fifty-six days in another. The fetuses always proved to be more or less macerated. In one of the two cases in which this sign was probable but not distinct, there was hydrocephalus. In two others, gas in the intestines obscured the findings. In two other cases the skull bones gaped; he has never beheld this in a normal pregnancy, and thinks that it can be accepted as a sign of death of the fetus at least eight days before. In these cases the fetus could not have been dead for more than eleven and thirty-six days. The pregnancy was in the eighth or ninth month and the fetuses were macerated and putrid. In two other cases the first examination was made during the interval between the lapping of the bones and the gaping; the roentgenogram showed apparently normal conditions as to the interline of the cranial bones, but after expulsion of the macerated fetus the bones had the same loose feeling inside the scalp as in the other cases. Comparison of roentgenograms from previous years revealed the lapping or the gaping of the cranial bones as never occurring in normal cases. The physiologic lapping of the bones during actual delivery can never lead to confusion. Another sign of the death of the fetus is the small size of the fetus in comparison to the phase of the pregnancy. The inability to obtain clear pictures of the skull bones—other conditions being favorable—suggests death and decalcification of the bones. The article is illustrated.

Pituitary Extract to Initiate Labor at Term.—Tholen gave an intramuscular injection of a small dose of pituitary extract to forty-eight women who were waiting for labor at term, usually after rupture of the bag of waters. Labor pains followed in from half an hour to an hour in 76 per cent of the primiparas and in 77 per cent of the multiparas. In five cases requiring premature delivery, the pituitary treatment had no apparent effect. In those cases in which only false labor pains followed the pituitary extract, a sedative was injected at once. The pituitary extract was preceded with castor oil, and the injection was repeated once or twice. The fetal heart sounds were constantly supervised, and no untoward by-effects were observed in either mother or child.

Hippocrates' Visit to Democritus.—Van Gils continues his study of the works of art of the Amsterdam school which date from the seventeenth century and portray what he accepts as the visit of Hippocrates to Democritus. They have hitherto been labeled "Saul's Visit to Samuel," "Antiochus' Visit to the Oracle," or "Heraclides' Visit to Democritus."

Tuberculosis in Goats and Goat's Milk Anemia.—Brouwer states that the second international congress on goat breeding was held recently at Freiburg, and Zwagerman and Scheurer presented a survey of the goat's milk anemia question, while Koestler reported a comprehensive physical and chemical study of goat's milk compared with cow's milk. De Blieck reported that he had found tuberculosis in twenty-four of about 500 goats examined in the Netherlands. Timmermans' figures in 1910 were 0.153 per cent of 49,030 goats in the Netherlands to that date.

*Hydrocephalus and Breech Presentation. T. H. M. Platte.—p. 664.
Two Attacks of Measles. C. C. van der Heide.—p. 665.

Preparedness for Marriage of the Female Sex Organs.—Van de Velde expatiates on the disease and unhappiness that might be prevented if sexual infantilism were corrected before marriage so that the sexual life could be normal from the first. He pleads for rectal examination to ascertain the condition of the sex organs, and appropriate treatment if found underdeveloped. The examination could be made without the girl's understanding its purpose, on the occasion of some indisposition or examination for life insurance. If the uterus is not over 3.5 cm. long, the condition is rudimentary rather than infantile, and not much can be hoped from treatment. But with infantile organs, ovarian treatment, diathermy and vibration massage of the uterus may accomplish much. The latter alone may suffice. The uterus is pressed against the abdominal wall by the finger in the rectum, and the massage instrument is applied to the abdominal wall. At necropsies in cases in which diathermy had been applied, he has been amazed at the intense circulation through the parts and the swelling of the tissues, testifying to the effect of the diathermy while warning of the necessity for caution. This triple treatment may cure menstrual disturbances and improve the general condition. He applies the vibration massage every day or two for seven to fifteen minutes, in a six or eight weeks' series, with a second series at need, a long pause between.

Mechanism of Diabetes.—Sybrandy explains that the hyperglycemia in diabetes is due to the defective metastasis of glucose, that is, the distribution of glucose to the liver, heart and other tissues. Insulin promotes this metastasis of glucose—the blood-sugar circuit, as he calls it—the liver and muscles constantly producing glucose which is transformed into glycogen and back again.

Means to Reduce Intra-Ocular Tension.—De Jongh and Wolff announced in 1924 that the serum of animals which had been having convulsions contains some substance which seems to have the power to reduce intra-ocular tension. They proved this with secondary glaucoma in rabbits, and they here confirm these findings and also report the reduction of intra-ocular pressure in a rabbit with spontaneous, natural glaucoma.

Clinical Import of Cholesterol.—Brandes concludes the report on his extensive research on cholesterol with the statement that it has no value in the differential diagnosis of dubious gallstone cases nor in the prognosis in nephritis or diabetes. But in pernicious anemia, estimation of the cholesterol may be instructive. There is evidently some connection between cholesterol and the pernicious process, but its nature is not known. The attempts to treat pernicious anemia with cholesterol have never proved successful.

Mycoses.—Rademaker describes four cases of actinomycosis and two of bothriomycosis; in a third case, with the presumptive diagnosis of the latter, the affection proved to be molluscum contagiosum.

Delivery of Child with Hydrocephalus in Breech Presentation.—Platte introduces a trocar into the fetal skull through the mother's abdominal wall when all means to deliver the child without perforation have failed. The fluid spurts and the obstacle to delivery is thus removed.

THE RECOGNITION OF A BIOLOGIC DIFFERENTIATION IN THE WHITE BLOOD CELLS

WITH ESPECIAL REFERENCE TO BLOOD TRANSFUSION *

CHARLES A. DOAN, M.D.
NEW YORK

The development of the supravital technic for the study of living blood cells in vitro [1] has made available, for the first time, a simple, adequate method for the qualitative analysis of the white blood cells. It was the attempted application of this procedure to a study of the problem of the possible relationship of the white blood cells to the unexplained reactions following the transfusion of matched red blood cells that led to the results presented briefly at this time.

During some experiments on rabbits, several years ago, in which two groups of individually matched animals were used for repeated transfusions of blood, it was noted that there was a marked difference in the clinical manifestations, following transfusion in certain recipients. A study of the peripheral blood at frequent intervals during the occasional, more severe, clinical reactions following the matched blood transfusions directed our attention to the white blood cells. Not only did the animals almost always show quantitative diminutions in the white count, but in the supravital preparations there was marked evidence of destruction of white blood cells in the greatly increased amount of cellular débris, obviously of such origin, in the blood. This condition was in sharp contrast to the findings in leukopenic states, caused by other experimental procedures, in which the decrease in the total white count is not accompanied by any evidence of increased cellular disintegration, the transitory nature of the leukopenia in many instances indicating simply a circulatory disturbance, with an accompanying redistribution phenomenon. When blood from a rabbit is given to a recipient, in which the serum agglutinates the red blood cells of the donor, a sudden convulsion, followed by immediate death, is the result, often while the blood is still being injected. On the other hand, the reactions that we have observed accompanying the evidences of the destruction of white blood cells come on within from half an hour to two hours of the transfusion, and are typical of foreign protein reactions in general. It was thought that if the recipient's serum should be found to be specifically leukotoxic in character, the disintegrating white blood cells could conceivably form the source of the foreign protein in these reactions. As a simple, practicable and quick means of determining in vitro *the probable relative toxicity of specific serums to* specific white blood cells, when transfusion is contemplated, the following procedure was devised and has been used for the past year and a half in both theoretical and practical determinations.

TECHNIC

First, it is essential that the slides and cover glasses for the supravital preparations be free of grease and neutral in reaction (nonacid). Glassware is placed in a saturated solution of potassium bichromate in concentrated sulphuric acid for three or four days, and then washed in running tap water for twelve hours. It is rinsed in three changes of distilled water; the slides stand over night in the last change. It is stored in 80 per cent alcohol. It is dried with clean, new gauze and flamed. If a dye is used (it is not essential), vital neutral red is recommended. Grübler's prewar, vital neutral red is made up in saturated solution in neutral absolute alcohol.[2] Twenty-five drops of the saturated solution in 5 cc. of absolute alcohol gives a nontoxic concentration of the dye for use in examinations of normal blood. The slides are flooded with the dye and then drained; they are allowed to dry in the upright position, which insures a thin, even film of the dye on the slide. A film of blood made on such a slide, when kept in the warm box at 37.5 C., will show viable cells for as long a period as a film made without the dye. Moreover, the dye makes the individual cells much more easily visible and the identification of cell types more certain. The prime requisites, it is to be remembered, however, are motility of the cells and freedom from any technical cellular depressant. The weight of the cover slip will cause the drop of blood to spread to the desired extent, provided the glassware is clean. It is sealed with petrolatum of a higher melting point than the temperature at which the examination is to be made. Either a warm box or a warm stage, preferably the former, may be used. The uniformly constant temperature conditions are an essential.

The cover slips are prepared in a similar way. They are flooded with the citrated or oxalated plasma or blood serum that has been secured for grouping the red blood cells, and drained to one corner in the vertical position, the drop of plasma that forms there being carefully removed with a fine capillary pipet. This is necessary in order that the unevenness attendant on the drying of a large drop of plasma at that point may be avoided. From the finger or ear of the person whose white blood cells are to be tested, a drop of blood is taken directly on the cover slip, prepared with the dried serum, and dropped gently on the slide. If the blood does not promptly spread into a thin, even film, slight manipulation from the side, never a pressure from above, may be used. Immediately, on the same slide, and from the same or a subsequent drop of blood, the control film is made with a plain cover slip. Both are sealed with petrolatum, and, under proper temperature conditions, the control slip is looked at first, to make certain of the viability of the leukocytes. It is the comparison or contrast between the number of viable cells in the two preparations on which depends the determination of the compatibility of the plasma in question. Oxalate and citrate anticoagulants in themselves do not affect the white blood cells in this test. However, as will be seen from table 1, when a blood is leukotoxic, citrated or oxalated plasma is doubly destructive to the susceptible white cells. At certain times there are physiologic showers of the "nonmotile" leukocytes, described by Sabin and her co-workers [3] in 1925, which must be differentiated from the white cells specifically affected by the incompatible blood plasma. Both by the difference in physical characteristics and by their presence and number in the control film, it is readily possible to eliminate such preparations as *pseudopositives*. If the control film, at any time, contains a high percentage of the "nonmotile" leukocytes, it is advisable to make a second duplicate preparation, as this particular phase of the polymorphonuclear leukocyte is transitory and does not reflect the plasma effect so readily as does the actively motile form.

* In cases in which no qualitative changes were noted in supravital studies, the total counts of controls with acetic acid only and of the cells exposed to serums ran parallel over corresponding twenty-four hour periods.

SPECIFIC LEUKOTOXINS IN HUMAN BLOOD PLASMA

As in the case of the red blood cells, so with the white blood cells, certain serums have a much more decided and rapid agglutinative effect on the red cells, or a disintegrative effect on the leukocytes, than others. When the bloods are compatible for leukocytes, all the different types of white cells are as motile as in their own plasma. In the majority of instances, when the white blood cells of one person are affected by the dried plasma of another individual, the effect is immediate and unmistakable; i. e., as soon as the preparation can be placed under the microscope, there is no doubt of the serious depression in activity of the leukocytes; many may be rounded up or fixed in the act of motile elongation or irregular, pseudopod formation; others, with increasingly sluggish movements, indicate their susceptibility and gradual yielding to some foreign depressant. It is not unusual to find all the leukocytes rounded up and shrunken, with irregular edges, as if becoming dehydrated. In the majority of instances, just preceding, accompanying or soon following this rounding up of the polymorphonuclear cells, with com-

* In the first two instances it will be seen that sodium citrate increases the effect of an already foreign serum, while the last case, in which there the fourth series of observations may be noted. In making the practical clinical test it is, of course, necessary only to make observations on two

plete cessation of all motility, appear vacuoles of increasing number and size, staining with the neutral red. These are probably vacuoles of degeneration and mark a further stage in the process of disintegration. In table 2 it will be seen that in one case cited (serum T 4 vs. cells T 6) the number of vacuolated cells, on immediate observation, was large. A nucleus with scattered granules, evidencing a ruptured membrane, gradually becomes a more frequent finding in such a film on standing. This indicates not only that the motility of the leukocytes is inhibited, but also that there are eventual cell rupture and disintegration, as the end-result of the exposure to these leukotoxic serums.

---

[3] Sabin, Florence R.; Cunningham, R. S.; Doan, C. A., and Kindwall, J. A.: The Normal Rhythm of the White Blood Cells, Bull. Johns Hopkins Hosp. 37: 14-67 (July) 1925.

It is not only the polymorphonuclear leukocytes that are visibly affected by the occasional incompatible plasma. The lymphocytes lose all motility and perhaps are the first to show the effect of an unfavorable environment. We recognize in normal blood films three rather distinct sizes of lymphocytes, which have been separated, for convenience, into the small, the intermediate and the large. Many of the small, most of the intermediate, and only an occasional large lymphocyte show active motility. The type of movement of the leukocyte is that in which there is a marked forward streaming of the cytoplasm, as the pseudopodia advance, while the nucleus seems to be passively dragged along in the rear of the cell. In contradistinction to this pseudopodia-like motility of the cytoplasm of the polymorphonuclear cells, the lymphocytes move with the nucleus in the front end of the cell, seeming to be as actively involved in the motility as the cytoplasm itself. The nuclei show constant, inherent changes in shape as the cell advances, the cytoplasm following along to the rear. In our preparations the first, and in some instances the only, thing to be seen for some time is a rounding up of all lymphocytic nuclei and a shrinking of the whole cell, so that all appear as static small lymphocytes. However, the lymphocytes seem much more resistant to the disintegrative phase later.

The monocytes assume all manner of bizarre shapes, again suggestive of dehydration of the cytoplasm. They appear crumpled, fluted, with the centrosphere the focus or center of the peculiar, cracking cytoplasm. All motility is, of course, gone.

The leukotoxic effect of specific serums does not parallel the agglutinative phenomenon, as seen in the red blood cells. In every instance we have ascertained the red cell grouping of the individuals by hanging drop preparations. The dried serum of the cover slip preparations also causes agglutination of the red blood cells in the instances in which the groupings are incompatible. It is striking to see complete clumping of the red cells, with the white blood cells in the clear interspaces as actively motile as in the control, in which the red cells are evenly distributed. Conversely, it is just as striking to find no effect on the distribution of the red cells in a vital film, and yet to observe all the white blood cells inactive and undergoing the disintegrative changes already described.

As an in vitro quantitative check on the apparent qualitative changes leading to disintegration of the white blood cells, already observed, susceptible blood cells were diluted with serum in a series of white cell counting pipets. Counts were made at successive intervals, contrasting with controls diluted only with acetic acid in the usual way. Table 1 indicates the quantitative differences that were found. It will be remembered that quantitative changes in vivo had been observed and recorded in the earlier transfusion reactions.

In one instance, an original total white blood cell count of about 7,000 had decreased 20 per cent the first hour and a quarter, approximately 50 per cent after three hours, and 80 per cent after twenty-four hours. In another case with 6,000 total white blood cells originally, after four hours 20 per cent, after five and one-half hours 42 per cent, and after twenty-four hours 60 per cent had disappeared. These observations were made at room temperature, and under conditions presumably not so favorable for the full toxic effect of plasma on transfused leukocytes as would avail within the body. The cells resisting disintegration longest were lymphocytes, although obviously affected qualitatively.

In order to determine whether we were dealing with a particular leukotoxic substance of definite concentration in the serums that seemed to produce these effects on foreign white cells, various dilutions of the concentrated serum were made, and a series of consecutive

is no incompatibility, shows no inherent anticoagulant effect. The large percentage of vacuolated, disintegrating polymorphonuclear neutrophils in preparations, the control and the undiluted serum or plasma, dependent on whether the transfusion is to be direct or indirect.

drops of blood was taken at the same time and exposed, first, to the undiluted, dried serum, and then to the same serum at 75, 50, 25 and 10 per cent of the original strength. Table 2 indicates that the leukotoxic effect is directly proportional to the concentration of the foreign serum, but that anticoagulants increase the degree of injury to already susceptible cells. This probably means that greater importance will attach to the state of compatibility of the serum of the recipient than to that of the donor, just as group IV in the red cell classification (Moss) is used as a universal donor, even though the serum contains agglutinins against the other cell groups.

This leukotoxic property of certain bloods is thermolabile. Heating for one hour at 60 C. in a water bath inactivates the plasma approximately 90 per cent, in comparing with the control and contrasting with the fresh, unheated serum.

We have now kept serum dried on cover slips for one year, and when contrasted in its effect with the fresh serum of the same individual, the former has been found to have lost about 90 per cent of its original effectiveness. The serum in sealed ampules deteriorates likewise. Thus, fresh serum is desirable and necessary in making tests for compatibility for transfusion.

Ross,[4] in 1911, discussed the relationship of the blood plasma to the length of life of the white blood cells in different individuals in both health and disease. He determined the length of life of a healthy person's leukocytes, when resting in their own plasma, to be between twenty-four and eighty-six hours. In the case of a healthy person's leukocytes versus another healthy person's plasma, the length of life was found to be between fourteen and twenty-eight hours. He concluded that "the plasma of one person is poisonous to another person's leukocytes." The present observations, however, tend to differentiate and group individuals on the basis of whether their leukocytes are susceptible to foreign plasma or not.

Thus, the effort has been made to determine the classification of individuals with reference to the white blood cells on some such basis as is recognized for the red cells. This has not been so easy, however, as it was in the earlier grouping of the red blood cells. At the one extreme, in the present series of forty persons are to be found about 40 per cent whose serum or white blood cells seem to be mutually compatible with all others. At the other extreme are 5 per cent whose white blood cells seem to be susceptible to all serums, or to practically all serums to which they have been exposed. Between these two extremes there appears a variety of reactions which can be explained only on the hypothetic presence of at least three different leukotoxic components in the cells, with their complements in like number variously distributed in the serums. On this hypothesis there would be twenty-seven combinations biologically possible, as recognized by Guthrie and Huck for the red cells. However, the frequent occurrence of a larger number of these possibilities with the white blood cells than with the red cells is indicated by our observations. We have found examples of nine different combinations in the remaining 55 per cent of our forty subjects. However, to attempt to assign arbitrary group designations to each would tend at this time only to complicate and confuse rather than to simplify and clarify the application of the principle.

As a consequence of this larger number of possible combinations, occurring regularly, and because of the necessity of using fresh serums for determining the compatibility, it is not practical to determine the group of each donor and recipient. Rather, we would suggest the direct cross matching of the white cells and serum of donor and recipient after the red cell grouping has been determined. With professional donors, it would soon become evident whether they fell into the general group of universal donors (A) or into the universally leukotoxic class (Z). It would seem, on the basis of the observations to date, therefore, that direct cross matching of the white blood cells, immediately prior to transfusion, is desirable and advisable as a further aid in avoiding the possibility of an unpleasant or conceivably fatal reaction. It is well recognized now that, for safety, direct cross matching of the red blood cells is desirable, in addition to a knowledge of compatible groupings.

HUMAN BLOOD TRANSFUSIONS

Guthrie and Huck,[5] in a review of the subject of the reactions following transfusion in relation to their recent survey of the existence of more than four iso-agglutinin groups of red blood cells, remark:

> The really serious reactions, although more uncommon, are of much greater importance. Those which concern us chiefly at the moment are such as may reasonably be attributed to incompatibility, as reckoned by the standard of iso-agglutination. Before passing to this aspect of the question, however, we wish to call attention to another phase which is usually overlooked. Most of us have a tendency to view transfusion as a ready means of correcting a deficiency in red blood cells, and so regard the material, administered intravenously, merely as a suspension of red cells, habitually disregarding the other ingredients, or at least minimizing their importance. We rarely consider the fact that the patient receives plasma, leukocytes, and more or less damaged platelets, in addition to the needed red cells. Concerning the effect of the leukocytes, not much evidence is available, but it has been shown that the platelet fraction may possess some toxicity.

In the final analysis, the real proving of the in vitro evidence for white blood cell incompatibility lies in its application to the therapeutic procedure of blood transfusion, under as carefully controlled conditions as it is possible to secure. The ideal test is, of course, that in which repeated transfusions are given to the same recipient, the consecutive donors differing only in their white blood cell compatibility, the technic of procedure in the transfusion being the same in all instances.

During the past year we have followed the cases of transfusion in the Thorndike and Fourth Medical services of the Boston City Hospital with reference to the procedures outlined above. In three instances we had opportunity to give to the same recipients repeated transfusions over a period of weeks. In one case, each of two transfusions was given from donors with both red and white blood cell compatibility in in vitro tests, and without any reaction. We have considered, singly or collectively, a rise of 2 degrees in temperature, with chilling and subjective discomfort, and marked white blood cell fluctuations, as constituting a reaction. In two instances, two transfusions were given at ten day intervals, the first donors being in each case incompatible only as to the white blood cells from in vitro tests. Severe reactions followed, one proving almost fatal. The second donors in each instance were both compatible as to red and white blood cells, with neither recipient showing the slightest reaction. All transfusions in the cases just cited were indirect, with citrated blood, and were given personally or with every possible detail personally checked. In a small series of ten single, indirect transfusions, seven cases in which there was compatibility of both red and white blood cells with in vitro tests showed no reactions. In two instances in which there was incompatibility only in the white blood cells, according to the preliminary tests, reactions occurred. In one case in which the white cells showed complete compatibility between donor and recipient, we observed a severe reaction. This individual proved, eventually, to be of an atypical group II in the red blood cell grouping, and ten different donors were tried before finally one could be secured with whose red blood cells there was not agglutination in vitro. In this instance, it is an open question as to what the cause of the reaction may have been, though from tests both before and after transfusion, the white blood cells of both donor and recipient were entirely compatible.

[5] Guthrie, C. G., and Huck, J. G.: On the Existence of More Than Four Iso Agglutinin Groups in Human Blood, Bull. Johns Hopkins Hosp. **34**: 37 (Feb.), 80 (March), 128 (April) 1923.

Minot and Isaacs[6] recently reported an interesting case from the Huntington Memorial Hospital, Boston. They arranged to transfuse 500 cc. of blood from a patient with chronic lymphatic leukemia into a recipient with lymphosarcoma. We were invited to follow the case with supravital studies. In vitro tests showed the white blood cells of donor and recipient to be entirely compatible. Both were of group IV (Moss) red blood cells. The donor had a white blood count of 89,000 just prior to transfusion, of which 95.6 per cent, or 85,200, were lymphocytes. The recipient had 6,400 white blood cells per cubic millimeter, only 992 of which were lymphocytes. Immediately following the direct transfusion of 500 cc. of blood, the recipient showed 8,800 white cells per cubic millimeter, with 3,740 lymphocytes; one hour later, 5,600 cells with 1,428 lymphocytes, and two hours and fifteen minutes after the transfusion, 6,200 cells, with 961 lymphocytes. Nor was there, at any time, evidence of any reaction. Furthermore, there was no evidence of cellular disintegration in the supravital studies made all that day. We have here a case in which there was a rapid elimination, from the peripheral blood, of lymphocytes, but without observable disintegration and without reaction, a striking contrast to the disintegrative phenomena which we have observed coincident with certain reactions.

There are too many different factors entering into each transfusion of blood to attribute to any one of them the full responsibility for unfortunate and sometimes dangerous reactions. Also, it is too difficult to control all the variables in technic and in chemical and cellular constituents of the individual donor's blood to assure a complete elimination of danger. But, as we learn to eliminate one by one the possible sources of error, particularly in application to those cases of dangerously weakened patients in which successful transfusion may mean life, but even a mild reaction death, the responsibility lies with the one who does not make use of every available safeguard.

The possible application of a recognition of this biologic incompatibility of the white cells in certain human bloods to the development of hypersensitiveness after repeated transfusions, to skin grafting and to other procedures is suggestive.

SUMMARY

1. There seems to be a definite incompatibility between the blood plasma of certain individuals and the white blood cells of others, as shown by simple in vitro tests.

2. A definite biologic classification of individuals according to white cell compatibility is difficult, because of the fact that at least twenty-seven different combinations are possible, many of them not infrequent. Approximately 40 per cent of the group of forty persons investigated may be considered universal donors (group A); 5 per cent seem to have cells susceptible to all, or nearly all, plasma (group Z); nine different combinations are represented in the remaining 55 per cent, to which no arbitrary group designation has been assigned at this time.

3. The added *precaution of ascertaining the relative* compatibility of plasma and white cells by direct matching, preliminary to transfusion, particularly in cases in which extreme weakness makes imperative a successful operation, is advisable.

PNEUMATIC RUPTURE OF THE SIGMOID

REPORT OF CASE

F. B. BLOCK, M.D.
AND
M. I. WEISSMAN, M.D.
PHILADELPHIA

The subject under consideration is that type of injury of the lower part of the large intestine which is caused by trauma resulting from the careless use of compressed air. The first complete review of this relatively rare injury was published by Andrews[1] in 1911, in which he reported a case with operation and recovery together with a collection of fifteen additional unpublished cases.

REPORT OF CASE

A man, aged 45, a machinist, admitted to the Jewish Hospital, Dec. 14, 1925, at 4 p. m., had been injured about two hours before. While standing at work with a compressed air hose, one of his fellow workers, as a practical joke, placed the nozzle of the air hose about an inch from his rectum. The patient had his clothes on and states that the nozzle, which was about one-fourth inch in diameter applying a pressure of about 125 pounds, was placed diagonally against the anus. He immediately became dizzy, staggered, and fell to the floor unconscious. When he became conscious, about twenty minutes later, he walked with assistance to a first aid station about a block away. During this walk he complained only of having a sensation of being blown up. He did not vomit or feel nauseated, but had difficulty in catching his breath. At the first aid station the physician applied hot compresses to the abdomen, but he obtained no relief and was then brought to the hospital. Examination in the receiving ward showed that the patient was somewhat cyanosed, and his respirations were slightly increased, being mostly of the thoracic type. The heart sounds were scarcely audible. The temperature was 94 F.; pulse, 76, and respirations, 28. The abdomen was enormously distended, it was tympanitic all over, and the skin was very tense. A rectal tube was inserted without any effect on the condition. The patient stated that he had not passed any flatus since the accident, nor had there been any discharge of blood from the rectum. There was no peristalsis audible. About 5:30 p. m. he began to complain of abdominal pain for the first time. The abdomen became more tense and the cyanosis deepened. As there was not the slightest improvement in his condition, operation was decided on and was begun at 7:30 p. m., five and one-half hours after the accident.

---

[1] Andrews, E. W.: Surg. Gynec. Obst. **12**: 63 (Jan.) 1911.

When the peritoneal cavity was opened there was a rush of air with a whistling sound, and coincidently the abdominal tension entirely disappeared. The intestines were moderately injected, and there was a small amount of thick bloody fluid in the peritoneal cavity. The patient was placed in the Trendelenburg position and the pelvic portion of the bowel was exposed. Slightly above the junction of the sigmoid, with the rectum on the left side, there was an irregular perforation of the bowel with a diameter of about 25 mm., together with a laceration of the mesosigmoid about 2 inches (50 mm.) long. Through this opening fecal material was escaping into the peritoneal cavity. In addition to this, there were four longitudinal lacerations on the lower sigmoid and upper rectum involving the muscular coats of the bowel but not extending into the lumen. These lacerations, together with the perforation, were sutured with catgut and then reinforced with Pagenstecher-Lembert sutures. A jejunostomy was made as a prophylactic measure, and the abdomen closed with a rubber drainage tube in the pelvis. The patient was returned to bed and placed in the extreme Fowler position and given continuous hypodermoclysis of physiologic sodium chloride solution containing 1 drachm (4 cc.) of 0.5 per cent procaine to each thousand cubic centimeters of the solution. Morphine sulphate, one-sixth grain (11 mg.), was given by hypodermic injection every four hours, while the respirations remained above 20 per minute. Nothing was given by mouth until the second day, when he was allowed to have water freely and the hypodermoclysis was then stopped. The patient was given a semisoft diet on the fifth day, a soft diet on the ninth day, and a light diet on the thirteenth day. The enterostomy tube was out on the eighth day; the drainage tube was completely removed on the thirteenth day, and the patient was then allowed out of bed. Up to this time his temperature never rose above 101 F.; the pulse remained below 110 and the respirations below 30 a minute. Jan. 8, 1926, the patient developed some pain in the right testis, the temperature rose to 103, and the pulse increased to 115 a minute. A diagnosis was made of a right epididymitis secondary to a cystitis resulting from catheterization. The temperature was septic until January 17, when the patient's condition again became normal. January 20, he was about to be discharged from the hospital when he began to complain of pain in the upper abdomen and vomited. This continued without relief from gastric lavage, and the following day the temperature dropped to 97 F., the pulse increased to 112, and a diagnosis of acute intestinal obstruction was made and a second operation performed; this revealed the small intestine strangulated by three bands at the site of the wounds in the large intestine. These bands were ligated and divided, and the abdomen was closed without drainage. Convalescence following this operation was entirely normal, and the patient was discharged from the hospital in good condition, February 7, fifty-five days after admission.

DESTRUCTIVE FORCE OF COMPRESSED AIR

In analyzing the subject of pneumatic rupture of the bowel, we note that the majority of the cases were caused by the so-called practical joker, a man who plays pranks on his fellow workers with an air hose, and a few cases were caused accidentally by men cleaning their clothes with the air hose. It is evident that this practical joking must be common, especially with the ever increasing use of air under pressure in our modern industries for drills, riveters, cleaning of cars, machines and barrels, and probably many more trifling or minor accidents have occurred which are not reported. In all the cases cited the air had to pass through one or more layers of cloth to enter the anus, yet this obstruction did not seem to interfere with its serious effect. In several of Andrews' cases and in some of these of Bendixen and Blything,[2] as in our own, it will be noted that the compressed air nozzle was at least an inch or more from the body. Why is it, then, that we have such a destructive force in the application of compressed air? Andrews' explanation is more than convincing: First, from 100 to 125 pounds of air will form a solid column of air several inches in advance of the hose or nozzle which would almost act like a solid body, forcing open the sphincter muscles. Secondly, the anatomic arrangement of the perineum is such as to facilitate the concentration of the air pressure at the anal orifice. This anatomic condition is a peculiar formation of the pelvic floor, forming a funnel, whose apex is at the anus; the confined air, expanding in this funnel, will force the anus open without having the end of the pipe accurately adjusted to the anus. With the involuntary contractions of the levator and sphincter muscles, the space between the buttocks would be narrowed and the funnel deepened, thus confining the escaping air laterally and leading it the more quickly into the bowel. Thirdly, Andrews has shown by experimental work that it took only from 7 to 12½ pounds of pressure to rupture a piece of human intestine.

With the exception of one or two cases reported with bruises around the anus, the majority of cases revealed pathologic lesions intra-abdominally consisting of hemorrhage in the serosa, lacerations of the serosa and muscular coat with bulging of the mucous membrane, or complete rupture of the bowel through the serosa, muscular coat and mucous membrane as in our case. In nearly all cases the sigmoid was affected. The descending transverse or ascending colon, together with the small intestine and mesentery, may show signs of injury.

Pain was the first symptom complained of in the majority of cases, although in ours and a few other cases it did not come on until a few hours after the accident. The pain is severe and continuous in character. The face is usually sallow and somewhat cyanotic, the facial expression anxious and pinched. The abdomen is enormously distended, the skin very tense, the percussion note tympanitic, very little if any abdominal breathing caused by the pressure of the air against the diaphragm, and the patient may or may not be conscious. The temperature is usually normal or subnormal at the beginning, and later rises. The respirations are increased; the pulse rate increases somewhat, but its volume varies in the proportion to the amount of internal hemorrhage and degree of shock; nausea and vomiting are commonly present. Rectal hemorrhage is usually absent.

With the history of working around air under pressure, with the characteristic barrel shaped abdomen with its tense wall and tympanitic note, the thoracic breathing and the general symptoms of an abdominal injury, the diagnosis should not be overlooked.

Of the twenty-seven cases of which we were able to collect reports, sixteen reported by Andrews, seven by Bendixen and Blything, one by Buchbinder,[3] our own case, and two additional unpublished cases that occurred in industrial plants in Philadelphia, the mortality was 70.3 per cent. Twelve of these patients were not operated on, with a mortality of 75 per cent. The mortality of the patients operated on was about 47 per cent.

SUMMARY AND CONCLUSIONS

1. Warning should be posted in all industries using compressed air.

---

[2] Bendixen, T. A., and Blything, J. D.: Surg. Gynec. Obst. 18:73 (Jan.) 1914.

[3] Buchbinder, J. R.: Pneumatic Rupture of the Intestine, J. A. M. A. 76:518 (Feb. 19) 1921.

2. A column of air under pressure rushing from a nozzle which does not touch the body may enter the bowel and cause fatal injury.

3. The diagnosis should easily be made from the physical findings.

4. The anus and rectum escape injury because of their outside support, the sigmoid being the viscus usually injured.

5. Prompt evacuation of the air by emergency puncture and early laparatomy offer the best chance of recovery.

SOME MISCONCEPTIONS REGARDING THE RELATION OF HEREDITY TO CANCER AND OTHER DISEASES

STUDIES IN THE INCIDENCE AND INHERITABILITY OF SPONTANEOUS CANCER IN MICE: TWENTY-THIRD REPORT *

MAUD SLYE
CHICAGO

A very serious handicap is met in the effort to make known the facts of heredity and to place these facts in their proper relation to other biologic data, for the purpose of establishing the exact value of heredity among the biologic influences, so that we may have a firm basis for further departure, and not be forced continually to replow the same ground. This is particularly true in attempting to establish the relation of heredity to disease.

This serious handicap consists in what may well be called fundamentalism in the scientific field; that is, preconceived ideas and prejudices, not based on scientific research, but instead on general impression, hearsay evidence and the like, handed on from one to another and thus established in general opinion.

Scientific terms, frequently misunderstood and misused by clinicians and research workers, form a strong background of entrenchment to prejudice and preconceived opinion. One of these terms is "eugenics," which has been used to mean anything from personal and social hygiene, and childbirth conditions, prenatal and postnatal, through to the real facts of heredity. These widely divergent usages of the word eugenics have led to a rather widespread confusion among terms as different in meaning as sanitary, congenital and hereditary.

Personal and social hygiene have much to do with good birth, and they do determine those conditions which are congenital. They can in no way determine hereditary characters. They may influence the extent to which hereditary characters can develop, just as conditions of wholly external origin, such as lack of food or lack of sunshine can determine after birth how far certain hereditary characters can develop.

A congenital disease is contracted in utero. Any disease that is hereditary is not so contracted, but instead is the result of characters derived from ancestral germ plasm, inherent in the ovum and in the sperm cell. By the right line of experimentation, hereditary diseases can be proved not to have been contracted in utero.

This word "congenital" is another of the much misused terms. I am quoting from remarks made at a scientific meeting in a paper whose object was the establishment of one of the "cancer germs" somewhat recently discovered. "The fact that cancer is hereditary has nothing to do with whether or not it is an infection, as we all know that syphilis is hereditary, and syphilis is a specific infection." Such confusion between "congenital" and "hereditary" is not infrequent, and it is destructive of any correct understanding of heredity and the bearing on the etiology of disease which any given type of true inheritance behavior may have.

Intra-uterine influences determine what shall be congenital. Such influences do not determine characters that are hereditary, as these, having been laid down in ancestral germ plasm, can be carried through many generations before their frank emergence. As I have stated in a previous paper,[1] such hereditary recessive characters as the tendency to albinism, the tendency to cancer, and the tendency to the dancing habit shown in the Japanese waltzing mouse, have repeatedly been held back in this laboratory for over twenty-five generations. Submerged beneath a dominant character, they are carried along through generation after generation by hybrid carriers wearing the dominant appearance, but they are always potential in the strain as long as hybrid carriers are bred with the dominant. When eventually two of these hybrid carriers are mated, the next generation will frankly show, in some of the offspring, this recessive character (albinism, cancer, the dancing habit, etc.) which has been submerged in hybrid carriers for any number of generations desired. Such behavior of any character takes it wholly outside the realm of the congenital and places it indisputably among the characters that are hereditary. This test of whether or not a character can be transmitted through generation after generation without its frank emergence should always be made in the study of the inheritability of any recessive character, in order to be certain that it is truly hereditary and not congenital.

STATISTICS

The question of the inheritability of disease types seems to be of interest both to the medical and to the lay mind. In view of this long continued and very general interest, it is striking how few adequate studies have been attempted in the question of the relation of heredity to any pathologic condition.

In the absence of such studies, it is equally striking how generally an "opinion" is held on the subject of heredity, when the question is raised in connection with any given type of disease. There seems also to be a strong desire to think that diseases have no hereditary basis, and a readiness to accept the opinion that any given disease is not hereditary without any adequate data whatever, whereas the most incontrovertible evidence that any disease is hereditary does not carry conviction to such minds.

For example, at the symposium on rickets held at the 1924 session of the American Medical Association, the unanimous pronouncement was made that rickets is not hereditary "in the true sense" (whatever that expression may mean), and an editorial accepting this pronouncement and rejoicing in it shortly followed in The Journal.

* Read before the American Society for Cancer Research, Albany, N. Y., April 1, 1926.

* From the Cancer Laboratory of the Otho S. A. Sprague Memorial Institute and the University of Chicago.

[1] Slye, Maud: J. Cancer Research, April, 1926.

This pronouncement was not the outcome of adequate heredity studies of rickets, but of the *opinion* of the speakers at the symposium, based presumably on dearth of direct evidence of inheritability in the particular rickets subjects handled in their service.

This illustration is typical of the method commonly in vogue in handling questions of heredity in relation to disease. I desire strongly to reemphasize the misleading nature of such extempore "opinions" on the subject of heredity, since heredity is a most profoundly determining factor in the nature and behavior of any disease, and pronouncements on the subject should be based only on intensive heredity studies.

Thus, the most serious of the obstacles in establishing the facts and influence of heredity is the very general misconception of the nature of heredity itself, and of the type of test that is adequate to prove the inheritability or noninheritability of any disease. One of the fundamentalist views concerning heredity is that if we study the two parents we have canvassed the field. It is therefore a matter of surprise to those who hold this point of view, when two black parent mice have white offspring; or two brown-eyed human parents have blue-eyed children, or two human or mouse parents without cancer have cancerous offspring. To be consistent in these cases would be to decide that black hair is not inheritable and that brown eye-color is not inheritable, since it is on such a basis that such investigators decide that cancer is not hereditary. Positive conclusions regarding heredity are frequently based on information concerning the parents only. Not infrequently, scientific investigators announce the inheritability of a disease on so inconclusive a test as mating two individuals with the same disease and finding that the immediate offspring also have the disease.

Some better informed statisticians would take the record not only of the two parents but also of the four grandparents, and with entire conviction they base their conclusions concerning heredity on these data. But it is easily possible, in heredity, that there should appear in the third generation a character shown by neither parent nor any one of the four grandparents, as shown in the accompanying diagrams.

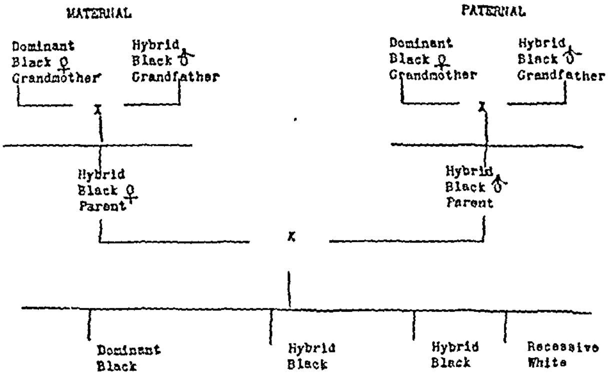

Fig. 1.—How albinos can be derived by the classic method, when neither parent nor any one of the four grandparents was albino.

As shown in figure 1, pigmentation is dominant over the lack of pigmentation (albinism). If, therefore, we mate two black mice, one of which is hybrid black (that is, carries albinism potentially) and the other purebreeding black, we shall get only black mice in their immediate offspring. One half of these will be purebreeding black, and one half will be hybrid black, and nothing in their external appearance indicates which are dominant black and which are hybrid black. If then we select for both parents of the next generation hybrid black individuals from such a cross, we shall get some albino mice in the immediate offspring.

Here, then, are albino mice readily obtained from ancestry which showed no white in either parent or any one of the four grandparents. By mating two of these whites, we shall immediately get a 100 per cent albino strain, which will remain 100 per cent albino, unless pigmentation is again hybridized in. Thus, by one *mating of two recessive albinos derived from hybrid* black is a strain, which had apparently been 100 per cent black, immediately converted in this branch into 100 per cent white.

Recessive Blue-eyed

Fig. 2.—How blue-eyed individuals are readily obtained when neither parent, nor any one of the four grandparents, was blue-eyed.

As shown in figure 2, again, brown eye-color is dominant over blue eye-color. If we select as grandparents one purebreeding brown-eyed and one hybrid brown-eyed individual for each pair, one half of their immediate offspring in each case will be purebreeding brown-eyed, and one half will be hybrid brown-eyed individuals, and nothing in their external appearance will distinguish the dominant brown-eyed from the hybrid brown-eyed. If two of these hybrid brown-eyed individuals are selected as parents, some of their offspring will be blue-eyed. Indeed, it is possible and frequently occurs that the only offspring born of a hybrid brown-eyed pair (when there are but few children) are blue-eyed.

We have, then, blue-eyed individuals readily obtained when neither parent nor any one of the four grandparents had blue eyes. By mating two such recessive blue-eyed *individuals, we shall in one generation convert* into a 100 per cent blue-eyed family what had until this mating apparently been a 100 per cent brown-eyed family, since double recessive parentage gives 100 per cent extracted recessive young.

In exactly this way, since cancer susceptibility seems to be recessive to cancer resistance, it is possible to get in the third generation cancerous individuals in which neither parent nor any one of the four grandparents was cancerous, but in which each parent was hybrid noncancerous, while in each pair of grandparents one individual was purebreeding noncancerous, and one was hybrid noncancerous, as shown in figure 3.

Here, then, are cancerous individuals readily obtained, of which neither parent nor any one of the four grandparents had cancer. By mating two of these recessive cancerous *individuals, we shall in one generation convert* into a 100 per cent extracted cancer strain what until this mating had apparently been a 100 per cent noncancerous family.

In the same way, that is, by the continued mating of purebreeding black with hybrid black, it would be possible to prevent the appearance of white for twenty-five generations, or for fifty or as many generations as is desired. As long as one parent in each pair is purebreeding black, no white will occur in the offspring. As long as one of the parents in each pair is hybrid black, white will be carried potentially in the strain. This can be done for any number of generations desired. But when, in any generation, both of the parents selected are hybrid black, white offspring will appear.

In the same way blue eyes can be kept out of the family, but will remain in it potentially as long as purebreeding brown-eyed individuals are mated with hybrid brown-eyed. But when two hybrid brown-eyed individuals are mated, blue eyes will appear in their immediate offspring.

In exactly this way, I have found that as long as one parent is a pure-breeding cancer-resistant individual, no cancer will appear in the offspring. As long as one parent is a hybrid cancer-resistant individual, cancer susceptibility will inevitably be carried potentially in the family, through the hybrid cancer-resistant individuals, for any number of generations. When finally two hybrid cancer-resistant individuals are mated, some of their immediate offspring will be cancer susceptible. That is, in every character transmitted by heredity, cancer or any other character, whatever its nature may be, as long as a purebreeding dominant is mated with a hybrid carrier, the recessive character will not appear, but will certainly be transmitted through the hybrid carrier for any number of generations, while the mating is of this type. When eventually two hybrid carriers are mated, the recessive character will appear in some of the immediate offspring. In the chance matings of the human species, the mating of two hybrid carriers of any given recessive (like cancer) is almost certain to occur sooner or later. When it does, the recessive character appears in some of the children. This accounts for the sudden appearance of cancer sometimes in human families in which there has been no known cancer for two or more generations.

Fig. 3.—How cancerous individuals can be obtained by the classic method, when neither parent nor any one of the four grandparents had cancer.

When these facts of heredity are grasped, there is at once apparent the absurdity of attempting to settle the question of the inheritability of any character whatever by the statistical method. For while the statistician, endeavoring to settle the question of the inheritability of any disease, can perhaps get the death facts and the life facts of both parents and possibly of the four grandparents, and perhaps eventually even of all the great grandparents, he cannot discover which of these individuals are purebreeding resistant to cancer (or any other disease), and which are hybrid cancer-resistant, for there is no way to discover this fact except by the experimental method of selective breeding and analysis with the right number and the right kind of hybrid crosses.

Only by the experimental analytic method can the question of the inheritability of any character whatever be settled definitely. Prevailing monogamy in any species makes analyses very difficult.

EXPERIMENTALLY PRODUCED CANCER

In discussing the bearing of studies in experimentally produced cancer on the question of cancer heredity, let us briefly review the history of the fundamentalist reception of the demonstrated fact of the inheritability of cancer, and the facts of the experimental production of cancer.

When these studies in spontaneous animal cancer were first published in 1911, practically all other studies in animal cancer were being carried on with grafted tumors. It had been demonstrated [2] that the inheritance behavior of grafted tumors indicated multiple factors, paramount among which was a dominant, determining a successful "take" of grafted cancer in the first hybrid generation.

The fact that studies in this laboratory demonstrated the inheritance behavior of spontaneous cancer to be that of a simple mendelian recessive caused the fundamentalists to think that geneticists did not agree as to the behavior of cancer heredity. They therefore discarded the entire fact of the inheritability of cancer. As I have stated in a previous article,[3] the findings in these two lines of studies are in perfect harmony, since a "take" of grafted tumor depends on the normal regeneration of the host tissues, and a spontaneous cancer depends on the abnormal regeneration of the tissues. Both studies, then, demonstrate the dominance of normal regeneration over abnormal regeneration. And there is therefore not even disharmony in regard to the method of the inheritability of cancer for the fundamentalist to base his objections on.

Next in history come the so-called "spiroptera cancers" of Fibiger's work,[4] which were immediately taken by the fundamentalist as a proof that cancer could be experimentally produced in all subjects, and therefore was not inheritable, entirely disregarding the demonstrated inheritance behavior of cancer in every test made by every student of the subject. Fibiger's work, carried outside the inbred strain of rats in his own laboratory to wild Norway rats, other strains of laboratory rats and strains of mice, showed that spiroptera cancer was not produced in all subjects.

The results of his studies are thus in perfect harmony with heredity studies in grafted cancer and in spontaneous cancer; that is, spiroptera cancers were produced only in susceptible members of susceptible strains of susceptible races. The finished results of Fibiger's study of spiroptera cancer therefore left no ground for scientific opposition to the fact of the inheritability of cancer.

Bullock and Curtis' studies [5] in liver sarcoma in rats, following experimental feeding with tapeworm larvae, fall into the same class with Fibiger's results; that is, they also demonstrate dependence on hereditary predisposition for success in the experimental production of these tumors.

[5] Bullock, F. D., and Curtis, M. R.: J. Cancer Research **8**: 1 (April) 1924.

Next followed the tar cancers, first produced by Yamagiwa in rabbits, and now widely studied in rats and mice by perhaps the majority of the present day workers in animal cancer research.

It is too early as yet to say what the final residuum will be from the study of tar cancers, since so many of these studies are still under way. But whether or not it is eventually found that tar cancer can be produced in all subjects, the conclusion cannot decide the question of the inheritability of cancer, and must be in agreement with all other facts of cancer, one of which is its demonstrated inheritability.

No one can deny the inheritability of the tendency to grow hair, yet continued painting with sufficiently strong coal tar products destroys the hair-growing mechanism. In all probability, continued painting with sufficiently strong coal tar will destroy every inherited tissue and every inherited function of the body. That is, no tissue, no function and no tendency of the body is immune from destruction. Coal tar products of sufficient concentration are very destructive agents and undoubtedly can destroy the cancer-resisting mechanism.

Thus the method used in the experimental production of unions may be destroying the very tendency it attempts to test. Therefore, the question of the inheritability of cancer resistance cannot be settled by determining whether cancer can or cannot be experimentally produced by any given method in any given set of subjects, since there is not and cannot be any complete biologic control in the field of heredity in such studies, nor any certainty that it is only the inheritability of the tendency to cancer resistance which is being tested in such experimentation.

PUBLIC PROPAGANDA

Another type of obstacle in establishing the facts of cancer heredity is the extraordinary idea apparently prevailing in some minds that since human heredity cannot at present be controlled, because we cannot control and experiment with human matings, the demonstrated facts of heredity do not apply to the human species and may therefore be categorically dismissed. For example, note the statement recently made by Wood of the Columbia Institute of Cancer Research:[6]

> Of course, the animal experimentation done by Maud Slye in Chicago and by Bullock and Curtis in my laboratory have definitely proved that in animals a susceptibility to cancer is transmissible. Of that there can be no question. The breeding experiments, however, are so complicated and take so long that if they were applied to human beings it would mean that for the last 5,000 years both parents of these unfortunate human beings would have had to have cancer. That is a concentration of breeding which cannot occur in the human race. So the facts of the high incidence of cancer in their experimental studies cannot be applied in full value to human beings.

This idea, that to test the inheritability of cancer in man would take 5,000 years, with double cancerous parentage in each generation, has no scientific basis whatever. The second argument is equally untenable, for Wood says in effect that the fact that we cannot make a 5,000 year test of the inheritability of human cancer warrants us in discarding the facts of cancer heredity so far as man is concerned.

An answer[7] to this statement appeared in THE JOURNAL, part of which is repeated here.

> The 100 per cent cancer strains that have been produced in any laboratory have been produced from a double cancerous parentage somewhere in the line. But this does not mean that there must have been a series of double cancerous parentage for any length of time corresponding to anything like 5,000 years of human heredity, or even for more than one generation. *One generation of double cancerous parentage will produce 100 per cent cancer susceptible offspring,* exactly as double albino parentage for only one generation will produce 100 per cent albino offspring.
>
> The long series of many generations of 100 per cent cancer have been charted, not because countless generations were necessary to produce them, but to demonstrate that they actually were 100 per cent cancer strains and continued so for as many generations as we continued a double cancerous parentage. It is not alone these strains of double cancerous parentage which prove the inheritability of cancer, but still more potent in this proof is the behavior of cancer in hybridization.
>
> Only two generations of exact facts are necessary to demonstrate inheritance behavior where the cross is between a cancerous individual and a noncancerous individual who is not a cancer carrier. Three generations of exact facts—not of double cancerous parentage—are necessary to determine how cancer behaves in heredity when a hybrid carrier is mated with a cancerous individual, or with a noncancerous individual that is not a cancer carrier. This is true in mice, in man or in any other animal, or in any plant.
>
> The difficulty in studying human heredity is not that we cannot have double cancerous parentage, or any other type of double parentage for 5,000 years, but that we cannot get the exact facts for even one generation. It is because of this lack of exact facts and because we cannot experiment on human beings in this and many other lines that we must get our exact facts from animal experimentation.
>
> That we are justified in applying these facts, where they are basic biologic facts, is one of the best assets derived from the discovery of the fact of evolution.

I bring up the quotation from Wood again at this time because it represents the type of reasoning that has governed the pronouncements on the subject of cancer heredity, in the publications of the American Society for Cancer Control. These publications in their turn have annually governed the propaganda concerning cancer heredity, in the various cancer control meetings all over the United States, and they are, moreover, quoted abroad. Thus easily does the fundamentalist doctrine spread.

In no other field of scientific endeavor do we assume that, because at present we cannot make a particular test of a demonstrated scientific fact (such as controlling human matings), therefore it is not a fact and we can forthwith discard it, nor do we discard the conclusions of higher mathematics and of higher physics because they are complicated.

The great difficulty in the study of human heredity is that man is so long lived an animal that no one person can collect accurate data for three generations. But this does not mean that there are no heredity facts unbrokenly expressing themselves in the human species just as they do in other animals of a shorter life span, whose exact records are being taken. If we should establish permanent records of periodic examinations of each living individual and permanent recorded accurate necropsy findings of all dead, in three generations we should have valuable scientific data. These data would undoubtedly include matings of double cancerous parentage, matings of double noncancerous parentage, matings of noncancer with hybrid carrier, and matings of cancer with hybrid carrier. These are exactly the matings by which we test the inheritability of cancer in short lived animals, and such records, if accurately taken and correctly interpreted would furnish an equally exact test for the human species.

STRAINS SUPPOSED TO CARRY A FIXED CANCER PERCENTAGE

Another strong obstacle in the way of establishing a clear comprehension of the relation of heredity to cancer is the announcement by workers in heredity, and by other workers in medical research, of what they designate as strains of animals carrying a permanently fixed percentage of any given character, as, for example, cancer.

The literature has several instances of the announcement of strains carrying a fixed percentage of cancer, to which it is perhaps unnecessary to make reference here, except when the assumption of a fixed percentage of cancer within a strain has been taken as the single basis for further research, as in the recent work of Lynch[8] of the Rockefeller Institute and of Bagg[9] of Cornell Medical College.

The widespread use of tar cancers in current research and the marked success in obtaining high percentages of such proliferations have again strengthened in the fundamentalist mind the idea that cancer is not inheritable, irrespective of the fact of its demonstrated inheritability. This idea has urged on workers in cancer heredity the necessity of demonstrating the relation of tar cancer to cancer inheritance, and Lynch of the Rockefeller Institute has attempted to do this, using materials that were entirely unfitted for the problem involved.

Lynch used two strains of mice, one of which she designates as carrying a fixed high percentage of spontaneous mammary gland cancer, 65 per cent in bred females and 20 per cent in unbred females; and the other, as carrying a fixed low percentage of spontaneous mammary gland cancer, 28 per cent in bred females, and 4 per cent in unbred females. Her object was to determine whether or not painting with tar the skin of mice from these two strains would change the incidence of cancer within the strains, and whether the so-called high per cent cancer strain would show a greater increase in cancers than the so-called low per cent cancer strain.

As Lynch herself very aptly states, "To test the influence of heredity on the response of the skin to tar painting, it would be best to employ strains of animals exhibiting differences in the incidence of spontaneous cancer of the skin."

Not only would it be best in such a test to use as a basis of experimentation susceptibility to skin carcinoma, but it is futile to use anything else, since the tendency to other types and locations of neoplasms, such as mammary gland carcinoma, has no influence on the production of spontaneous skin cancer. Lynch's experiments, therefore, have no bearing on the problem attacked. Moreover, having designated her strains as 20 per cent and 4 per cent, respectively, of spontaneous mammary gland carcinoma in unbred females (thereby carefully distinguishing between the cancer rate in bred and in unbred females), she proceeds to use in the experiment, as she says, "approximately one-half males" *whose susceptibility to cancer of any kind has in no way been expressed.* She does not state the age of the mice used, although the average age for the appearance of skin carcinoma differs markedly from the average age for the appearance of mammary gland carcinoma, and the matter of age differences should be under careful control in such an experiment.

But the gravest objection to experiments of this kind is the assumption of fixed percentages of cancer within a strain that is not homozygous in regard to cancer. It is wholly unscientific to assume fixed percentages of any character within such a strain on the basis that, to date by the matings made, it has yielded such a percentage of the given character. The past history of cancer production within a heterozygous strain cannot scientifically be assumed as the certain future history of cancer within that strain, nor can it be taken as the criterion for the cancer behavior of any individual member of the strain, not subjected to analysis.

Every strain that is producing some cancerous and some noncancerous individuals is heterozygous to cancer, just as every strain that is producing some black and some white individuals is heterozygous to albinism. *Every noncancerous member of a heterozygous cancer* strain is heterozygous to cancer unless at least one parent of that individual was dominant noncancerous, and one half of those with one dominant noncancerous parent will be heterozygous to cancer, since the mating of a dominant with a hybrid carrier produces one-half dominant and one-half hybrid carrier. Any strain that has to date yielded 4, 20, 28 or 65 per cent of cancer, like Lynch's strains, is heterozygous to cancer, and the cancer potentiality of every one of its members is dependent wholly on what matings have been made, just as its future cancer percentage will depend on what matings may be made. In addition to its cancerous members, such a strain is made up of some dominant noncancerous members and some hybrid carriers, and nothing in the external appearance will distinguish between the latter two types.

As I have already pointed out in this paper, recessive characters, such as the tendencies to albinism, to blue eyes and to cancer, which are submerged in hybrid carriers wearing the dominant appearance, can be made to appear suddenly within a strain, by the mating of two hybrid carriers. It is thus shown to be possible to convert, by two matings, a strain heretofore always wearing 100 per cent of the dominant appearance into a strain expressing 100 per cent of the recessive.

We cannot scientifically say that any heterozygous strain inherently carries a fixed percentage of cancer. We can only say that during the life of the strain, it did, under the matings made and the handling given it, produce a certain percentage of cancer. We must at the same time admit that, with different types of matings and different handling, the same strains would have produced wholly different percentages of cancer. The very foundation, therefore, on which Lynch's entire experiment is based vanishes away. The problem can never be scientifically attacked by this method.

The work of Bagg of Cornell Medical College, reported at the 1925 meeting of the American Society for Cancer Research, is open to a similar basic criticism. Bagg's experiments were designed to test the relation between functional disturbances of the breast to the incidence of mammary carcinoma in mice. He says that "a carefully inbred strain of animals with a well known low rate of tumor incidence was selected." He does not state what this low rate was. The control group of mice showed an incidence of 5 per cent of breast carcinoma. These mice, he says, "were breeding normally; that is, the females were remated only after nursing their litters for about six weeks." Of course this method is in miniature the method of human breeding and it does not necessarily define normal breeding in mice. The group of fifteen mice subjected to various types of experimental dysfunction of the breast showed an incidence of 85 per cent of breast carcinoma.

---

[8] Lynch, Clara J.: J. Exper. Med. **42**: 829 (Dec.) 1925.
[9] Bagg: J. Cancer Research **9**: 498, 1925.

I do not find any suggestion by Bagg that his results had any bearing whatever on the question of the inheritability of cancer, or that they were intended to have such a bearing. The fact of the inheritability of cancer, however, has a marked bearing on his experiments. It must be that he recognized the necessity of taking advantage of cancer susceptibility, since he very wisely selected a strain that was yielding carcinoma of the breast. Had he sought results opposed to the fact of cancer heredity, he should have made his tests on a strain that was analyzed cancer free, and should have secured complete biologic control in every other element of his experiment.

His experiments, then, were apparently designed to test the relation of experimentally produced breast trauma to breast carcinoma, in strains predisposed to breast cancer. In this selected strain, predisposed by heredity to breast carcinoma, he found a greatly higher incidence of breast cancer in the individuals that he had selected for experimental breast trauma.

There are two pertinent suggestions to be made here:

1. As I pointed out in my discussion of Lynch's work with tar cancers, it is unscientific to assume a fixed percentage of cancer in strains heterozygous to cancer. The fact that a strain, under the matings made, has yielded a given percentage of cancer, for example, as in Bagg's control group 5 per cent, cannot be taken as the criterion for the future production of tumor in that strain, or the percentage of tumor production in any other group of any other individuals in that strain, unless every individual involved has been analyzed and his cancer potentiality has been definitely established.

Bagg's conclusion, therefore, that the 85 per cent breast cancer incidence in his experimental group was due wholly to experimental procedures lacks the same scientific basis lacking in Lynch's work. It is easily possible in a strain which to date has never yielded more than 5 per cent of breast cancer to secure suddenly 100 per cent of breast cancer by the right selective matings, or 85 per cent. It is not impossible that the fifteen mice selected for his experimental group were exactly the ones which under any handling would have produced breast cancer; and such a possibility should be ruled out by complete biologic control.

Any strain which to date has produced 5 per cent or 85 per cent of cancer, like Bagg's strains, is heterozygous to cancer, and no assumptions are warranted as to the cancer potentiality of any unanalyzed groups or individual members of the strain. Moreover, in all such experiments, these should be recognized the source of error, even in individuals examined at necropsy, of deaths from intercurrent disease that prevents cancer development.

I have for years been urging on research workers the necessity of using biologically analyzed stock for their experiments, instead of assuming that results secured on unanalyzed stocks are wholly due to experimental procedures.

2. So far as I know, there is no worker in cancer research today who does not recognize the necessity of stimulations, irritations or traumas, either minute or gross, as a basis for cancerous growth. The fact that various types of irritations play an important part in the causation of cancer in susceptible individuals is one of the best basic arguments for defining cancer as an abnormal regenerative process. This regeneration after trauma apparently is abnormal in these cancer susceptible subjects, because of the lack of a differentiating mechanism in the tissues. It seems to be this local lack of a differentiating mechanism in susceptible tissues that is the hereditary element in cancer susceptibility. That is, the type of local response made to a given type of irritation is determined by heredity, whatever the type of that irritation may be.

If Bagg had worked with individuals every one of which was analyzed as to its cancer potentiality, if he had selected groups exactly homologous in the matter of cancer potentiality, individual for individual, and with such groups of homologous individuals and with numbers large enough to make a test had obtained just such results as he did obtain in his experiment, he would have given us a scientific demonstration of the relation of these particular types of trauma to breast cancer causation in his tested strains. Such conditions would have constituted a complete biologic control for those particular groups of animals.

It is very easy to assume after any particular experimental procedures that the end-results are wholly caused by such procedures; but if animals are used which have not been analyzed in the potentiality being tested, there is no basis for such an assumption.

In this connection, it might be of interest to mention mouse 21663 of this stock. She was picked up when 2 weeks old, with two carcinomas of the mammary gland, 10 and 3 mm., respectively, in diameter. She lived one week more, and at necropsy and on histologic examination, proved to have two carcinomas of the mammary gland, bilateral kidney sarcomas (the left kidney almost entirely destroyed), and osteosarcomas of the fifth rib and of the spinal column. Needless to say, this mouse had not been mated, nor had her ovaries been experimented on by removal or otherwise. But she was the great granddaughter of female 12058 with sarcoma of the kidney, bilateral sarcoma of the uterus and bilateral sarcomas of the ovaries. She was the granddaughter, five generations removed, of female 26 with sarcomas of the kidney, ovary, liver and mesentery. She was the granddaughter, eight generations removed, of female 3 with a sarcoma-carcinoma of the mammary gland, a malignant adenoma of the liver and sarcoma metastases in the kidney, in a strain which was being deliberately bred for kidney and liver tumors, and in her ancestry there was considerable percentage of osteosarcomas. It is also of interest to note that exactly the types of so-called functional disturbance used in Bagg's tests in his groups 1 and 2, that is, early and constant breeding of young females with removal of the young immediately after birth, have in this laboratory never occasioned mammary gland carcinoma in analyzed individuals of analyzed cancer free strains.

Although Bagg himself did not assert that his results had any bearing on the fact of the inheritability of cancer, in the discussion of his paper Ewing[10] of Cornell Medical College took occasion to say: "Carcinoma has been developed in a strain of animals which had very little natural tendency to develop the disease. If there had been any congenital or hereditary characters in the development of these carcinomas, it does not appear in these experiments of Bagg's. He has watched this group of animals for thirteen years and has found a very low incidence of cancer, so I think that these experiments offer a somewhat difficult problem to those who believe in the congenital or hereditary incidence of cancer."

So far as I know, no research worker who has made any study of the incidence of cancer defines it as a congenital disease, so we may dismiss that portion of Ewing's remarks. Moreover, the inheritability of cancer is no longer a matter of belief, but it is a matter of exact demonstration.

Evidently, Ewing did not see the paradox in his first two sentences. For in the first he admits the strain used had a little natural tendency to carcinoma of the breast; while in the second, he says that no hereditary character in the development of the disease appeared in the experiment.

As I have stated, a strain which to date has been producing 5 per cent breast cancer can in one mating be changed to a wholly different percentage of breast cancer, and any experimental procedure which assumes the continuation of a fixed percentage of cancer in unanalyzed strains is based on assumption only.

Loeb[11] also, in attempting to demonstrate the relation of the ovaries to breast cancer incidence, used what he called "a strain of mice with a known high tumor incidence," and concluded from his experimental procedures that removal of the ovaries lowered the incidence of tumor within the strain.

As I have repeatedly stated since the first publication of this work fifteen years ago, the type of product within a strain depends on the matings within that strain, just as certainly as the type of chemical result depends on what chemical combinations are made. If we combine zinc with sulphuric acid we shall get one kind of result; if we combine it with hydrochloric acid we shall get a different result. In just this way and just as surely, if we mate an albino with a red mouse, we shall get one type of offspring; if we mate the same albino with a gray mouse, we shall get a different type of offspring. If we mate the same gray mouse with a first generation albino derived from red (and hence a hybrid carrier of red), we shall get entirely different results; that is, some red, in the first hybrid generation.

Any strain can in one mating be changed in the percentage it carries of any inheritable character, including cancer, according to the mating made. The greatest caution, therefore, will be necessary to secure complete biologic control, in any effort to discover the relation which experimental procedures of any kind may bear to the causation of cancers of any type or any location, or the relation of the basic facts of cancer heredity to such results. The assumption that fixed percentages of cancer can permanently define a heterozygous strain, or any group or any individual members of such a strain, will certainly have to be excluded.

We shall never get the right idea of heredity, and hence we shall never work out correctly the facts of inheritance and its complex and intricate influences throughout all organic response to every type of test, until we conceive of strains as plastic in every generation, susceptible of being changed by one mating of the right kind from 100 per cent of a character to zero per cent of that character, or to 50 per cent, and susceptible of being changed by a series of matings to any percentage desired. If this were not true, and if strains were fixed in the percentage they carried of any inheritable character, there would be no such thing as heredity, since the new hybrid mating would bring nothing to the strain; that is, the new individual would have no inheritance to offer.

ALL FACTS OF CANCER MUST BE CONSISTENT EACH WITH THE OTHERS

In the diverse lines of approach used by the many workers in any field of scientific research, there are sure to be made evident gaps in our knowledge. But these gaps do not entitle us to deny a scientifically demonstrated fact, because we cannot yet in our own minds make it accord with our own particular discovery or our own particular theory.

As in any other field of scientific endeavor, all the facts in the field of cancer research must be consistent each with every other. If it should eventually be possible to produce experimental cancer in every subject, this would not disprove the inheritability of cancer any more than the fact of the inheritability of cancer proves that it must be impossible to produce cancer experimentally in every subject. No biologist has ever made such an assertion. There must instead be a third fact that harmonizes these two. This third fact is already evident in the highly destructive nature of the experimental agents used, which may well destroy the cancer resistant mechanism or any other bodily mechanism. Spontaneous cancers do not arise in every individual, either in the human species or in lower animals even under identical conditions; this is a demonstration that there is a cancer resistant mechanism present in some members of every species. No amount of experimentally produced tumor can offset this fact. The explanation of these tumors will have to harmonize with it.

Again, if cancer should eventually be demonstrated to be a specific infection, this would not disprove its inheritability any more than the fact that the inheritability of cancer definitely proves that cancer is not a specific infection. There must be a third fact that would harmonize these two. That third fact is readily discerned even now in the hereditary basis of every organic response to every type of stimulation or irritation, whether it is a specific germ or anything else, although there is variation in the types of inheritance behavior, and apparently these variations have a bearing on the etiology of various diseases.

The third most frequent objection to the inheritability of cancer, namely, that although proved for lower mammals it does not apply to man, is answered by the fact of evolution. Similar tissues derived in the course of evolution from the same ancestry must respond in the same way as the ancestral tissues to the same types of stimulation. Only so could an unbroken series of organisms evolve each from the other.

The scientific method of procedure for those who cannot accept the evolutionary evidence is not categorically to deny what they cannot disprove and what has indisputably been found true by many workers, but rather to begin the measures which inevitably must produce scientific data for the investigation of heredity in man.

MEDICAL DIATHERMY IN KIDNEY DISEASES

GUSTAV KOLISCHER, M.D.
AND
ALFRED E. JONES, M.D.
CHICAGO

Medical diathermy, the heating within physiologic limits of bodily structures with high frequency currents, may be employed to advantage in glomerulonephritis and toxic nephrosis.

The efficiency of this therapeutic procedure depends on its judicious application according to the character of the case. Glomerulonephritis, whose essential feature is the more or less complete blockade of the glomeruli involved and the subsequent renal ischemia, is a condition in which the local administration of high frequency currents to the diseased kidney or kidneys may be beneficial. The heating causes the arteries, arterioles and capillaries within the area under the influence of the high frequency current to dilate, and is therefore apt to improve the impaired circulation. The clinical effect of this active hyperemia is readily observed. Following the diathermic treatment, the urinary output is raised; the content in the urine of liquid blood is promptly heightened, and the number of tiny coagula appearing in the urine is increased. In case a decapsulation of one or both kidneys is undertaken, the "sweating" of the denuded organs is enhanced by a subsequent diathermic treatment, as evidenced by the fact that the serum emanating from the point of drainage becomes copious and acquires a rosy hue.

The addition of diathermy to the standard antinephritic regimen seems to hasten the absorption of nephritic edemas. It is argued that diathermy is contraindicated in acute nephritis because it is apt to increase the renal bleeding and is also apt to raise the already high blood pressure, a symptom usually accompanying nephritis. Increased bleeding from a nephritic kidney may be looked on as therapeutically desirable, this forced flow being helpful in raising the exudative blockade within and around the glomeruli. The rise of blood pressure in nephritis may be considered a compensatory hyperactivity of the heart. A nephritic kidney offers increased resistance to the propulsion of the blood stream. In order to force the necessary amount of blood through it, an augmented heart action is essential for furnishing the proper renal blood supply. From either point of view, the objections mentioned cannot be upheld.

TECHNIC

The object being to heat the kidneys, they must be localized. This enables the operator to place the electrodes properly. While occasionally it may be feasible to locate the kidneys by palpation, the surest way of ascertaining their position is the taking of a roentgenogram. Incidentally, at times roentgen rays influence rather favorably the course of a nephritis by reducing the surplus of exudation that chokes the glomeruli. Electrodes of equal size, approximately of the dimensions of the kidneys, are placed opposite each other, one in front and one in back, including between them the organ to be heated. Blank metal electrodes are generally considered most satisfactory.

The dosage in diathermy for nephritis should be considered from two points of view. It is of course necessary to produce a certain amount of heat in order to answer the therapeutic purpose, but the influence of the heat on the heart must also be taken into account. In practically every instance of nephritis, the heart is involved to a greater or lesser extent. While it is true that moderate heating of the heart is beneficial in certain diseases of the heart, any excess of heating may lead to a rapidly developing fatigue of this organ. Therefore, if diathermy is applied to the left kidney, especially if it is high up in the diaphragmatic cupola, the amperage must be kept strictly within moderate limits. The same consideration also militates against a simultaneous diathermy of both kidneys, which may produce overheating of the thorax and subsequently of the heart.

Exceeding the safe limit is marked by restlessness of the patient, profuse perspiration and precordial anxiety. Prolonged sittings may lead to an undesirable accumulation of heat; therefore, it is advisable to restrict the initial treatments to about fifteen minutes. After the tolerance of the patient is established, the duration of each diathermic treatment may be extended if deemed necessary. There is no objection to the repetition of diathermic treatment every other day until the nephritic symptoms have receded. In nephrosis, direct heating of the kidney *a priori* does not hold out any promise of success, because in such cases vascular impediment is not a prominent feature; clinical experience bears out this theoretical reasoning. But diathermy may be used to advantage in a different manner of application. A charactertistic symptom of nephrosis is the retention of chlorides within certain structures of the body, among which the subcutaneous cellular tissue is prominent. These structures act as intermediary and under certain conditions as temporary depositories only for the metabolic end-products before they are carried by the blood stream to the kidneys for final disposal and elimination. This physiologic rôle of these structures is so pronounced that some authors call them the adventitious kidney. If for some reason the capillary complex of this system is depressed in its function, an excessive accumulation of chlorides will result which, finally leads to the establishment of edema. Capillaries and arterioles as a rule respond quickly to medical diathermy. Results may be expected in many cases, if the temperature of the whole body is moderately raised by the use of general diathermy, the so-called autocondensation. In addition the lower extremities, so prone toward development of edema, are separately heated at intervals by the high frequency current. If edema of the lower extremities already prevails, however, the amperage is kept within low limits, because an edematous skin is vulnerable.

The question concerning the amperage to be employed in each case cannot be answered *a priori* by quoting exact figures. Each diathermic apparatus is a unit by itself, and the resistance to the electric current offered by the body of the patient depends also on individual factors, among which the thickness of the layers covering the organ to be heated plays a prominent rôle. The safe procedure is to start with the minimum of current and gradually increase its volume until the patient reports a distinctive sensation of warmth but not of heat. After the tolerance of the patient is established, the readings of the amperemeter may be used in the following treatments.

CONCLUSION

There is no mysterious electrical influence brought to bear on the renal cells by diathermy; whatever benefits are obtained are due to the heat produced within the perirenal and the renal structures by the resistance these parts offer to the high frequency current forced through them. The efficiency of any antinephritic treatment depends to a great extent on its early administration, and the same holds good for diathermy. The sooner after the discovery of a nephritis it is applied, the more favorable will be the outlook. Medical diathermy is by no means a cureall or a specific for nephritis or nephrosis. It is simply a valuable aid and will furnish results only in combination with the other therapeutic measures indicated, such as removal of the etiologic infectious foci, the proper dietary regimen, the administration of cardiacs and diuretics and, if suggested by the prevailing conditions, nephrolysis and decapsulation.

SYMMETRICAL GANGRENE OF MALARIAL ORIGIN [*]

WILLIAM H. SLAUGHTER, M.D.
Surgeon, U. S Public Health Service
MOBILE, ALA.

The occurrence of gangrene following infectious diseases is not uncommon; but the occurrence of symmetrical gangrene as a complication in such conditions is comparatively rare and is barely mentioned in any of the textbooks. The occurrence of symmetrical gangrene in malaria, which is classified by Dieulafoy [1] under the infectious diseases proper to man, is mentioned by only a few authors; of all the complications and sequelae of malaria, gangrene is probably the rarest.

Brusa [2] reports a case of symmetrical gangrene in a child, aged 14 months, following measles; Learmonth,[3] a case of gangrene in the lower extremities in a child, aged 3 years, complicating scarlet fever which began simultaneously in the two limbs. Buerger [4] refers to gangrene as complicating syphilis, typhoid, influenza, typhus fever, cholera and scarlet fever during the period of convalescence; Darier [5] and Kerr [6] refer to thrombosis following typhoid, the former mentioning gangrene of the leg as a terminal result. Ransome and Corner,[7] after a diligent search in the libraries of the Royal Society of Medicine and of the Royal College of Surgeons of England in 1910, collected reports of eight cases of gangrene following convalescence from diphtheria, and added one additional case of their own. In seven of the nine, the leg was affected. Bailly,[8] in 1920, in an article on the occlusion of the arteries of the limbs in malignant diphtheria, collected reports of seventeen cases of gangrene from the literature and added one of his own. All were of the dry type. In two, the gangrene involved the upper limbs; in sixteen, the lower. In five cases, both lower limbs were involved. Barraud,[9] in 1904, made a summary of 103 cases of gangrene of the extremities following the infectious diseases in young patients. He chose young subjects for his study in order to exclude senile and presenile gangrene due to arteriosclerosis in older persons; he also excluded spontaneous gangrene resulting from Raynaud's disease. Of the cases recorded in the summary of 103, typhoid fever is given as the cause of gangrene in forty-four, typhus fever in eleven, measles in six, scarlet fever in five, pneumonia in five, acute articular rheumatism in five, influenza in two, diphtheria in two, erysipelas in two, malaria in two, pertussis, dysentery, relapsing fever, cholera morbus, varicella in one each, and various surgical conditions in fourteen.

Malaria is mentioned as a causative factor in symmetrical gangrene by Dana,[10] Castellani and Chalmers,[11] DaCosta,[12] Elliot,[13] Stelwagon,[14] and Church and Peterson [15] In 1869, eleven years before the discovery of the pathogenic agent of malaria by Laveran, Rey [16] published a report of the first case of symmetrical gangrene observed in a man who had had intermittent fever in Senegal and had suffered a relapse on his arrival in France Laveran [17] described one instance of gangrene of both legs as a complication of malaria. In 1875, Mourson [16] noticed a local asphyxia following an attack of intermittent fever and called especial attention to the coincidence. Fischer [16] also had seen a case of the same kind, and Calmette,[18] in 1877, devoted an article to reports of local asphyxia of the extremities in connection with malarial intermittent fever. Leloir [19] observed three cases which seemed to strengthen this conclusion.

Osler,[20] in 1900, reported a case of multiple gangrene occurring in estivo-autumnal malaria and involving the feet, hands, buttock and occiput. Examination of the blood revealed crescents and estivo-autumnal organisms in unusually large numbers.

Hammond,[21] in 1913, reported from India two cases of gangrene of the extremities—one with recovery, the other fatal. In the case ending in recovery, malignant tertian rings were found, "one corpuscle in every three" containing these forms; in the fatal case, the blood findings regarding the type of malaria were not recorded.

Paisseau and Lemaire,[22] in 1917, reported two cases of gangrene of malarial origin. In each instance the gangrene was symmetrical and involved the lower extremities. Both cases were fatal. Blood examination in each showed a severe infection with *Plasmodium falciparum.*

ETIOLOGY AND MECHANISM OF SYMMETRICAL GANGRENE

It is agreed that gangrene is due to lack of nourishment of the part affected. Symmetrical gangrene is usually of the dry type, because it is the result of an obstruction opposed to the inflow of arterial blood. According to MacCallum,[23] this may be an effect of the active contraction of the blood vessels through the intermediation of the vasomotor system, or to a complete obstruction or blocking of the artery by some foreign substance that is lodged there.

The arterial obstruction may, therefore, be due to: (1) constriction of the arterioles; (2) embolism, or (3) thrombosis.

1. *Constriction of the Arterioles.*—Darier,[5] Church and Peterson,[15] Greene,[24] Dennis,[25] Adson and Brown,[26] Kaposi[27] and Calmette[16] subscribe to the view that vasoconstriction may cause gangrene. Raynaud[28] held that the gangrene is probably caused by a tetanic condition of the great sympathetic nerve which in turn produces contracture of the arterioles. Trophic gangrene, in the opinion of Keene,[29] is probably caused by a spasm or paralysis of the arterioles, rather than through special trophic nerves governing nutrition, thrombosis preceded by nutritive alterations in the vascular intima being considered the most prominent factor. It is also his opinion that gangrene produced by cold or by long continued action of certain drugs, such as ergot, as well as Raynaud's gangrene, is explained in a similar manner, but he states that it is "a question as to whether the mortification is due directly to vascular spasm or arises secondarily from alterations in the intima followed by obstructive thrombosis, with the chances in favor of the latter."

Neuritis is regarded as one of the causes of symmetrical gangrene. It is so regarded by Pitres[30] and Vaillard,[30] whose views have not been generally accepted. Tyson[31] takes the view that the theory of arteriole spasm suggested by Raynaud himself best explains the condition. In nine cases of gangrene following diphtheria reported by Ransome and Corner,[7] one case is termed Raynaud's disease. It is important to differentiate the symmetrical gangrene of the extremities of the Raynaud type from the gangrene due to embolism and thrombosis. The differentiation has been pointed out by Osler,[20] who states that the phenomena of Raynaud's disease may occur as a sequence of any of the specific fevers, and that a large proportion of all the cases of local gangrene occurring during or after one of the fevers have nothing whatever to do with this affection. To aid in such differentiation is the fact that Raynaud's gangrene usually develops in paroxysms and all degrees may be observed, at times a simple asphyxia of the limb, at others an asphyxia followed by gangrene. Moreover, in Raynaud's disease there is possibly an accentuation rather than an absence of the arterial pulsations in the affected limb as found in embolism and thrombosis. In both embolism and thrombosis this absence of pulsation in the arterial trunks of the limbs is the one symptom, above all others, which most readily affirms the existence of such conditions.

2. *Embolism or Plugging of the Arterioles.*—"Embolism," as defined by Welch,[32] "is the impaction in some part of the vascular system of any undissolved material brought there by the blood current." In six of the nine cases of gangrene complicating diphtheria reported by Ransome and Corner,[7] the gangrene was due to embolism following cardiac thrombosis. The cause of cerebral attacks in malaria, according to Manson,[33] has been found on postmortem examination to be due to embolism by the accumulation of the malarial parasites in the capillaries of the nerve centers involved. Marchiafava and Bignami[34] state that the circulatory changes found in the brain capillaries may occur in other organs and systems. MacCallum,[23] in explaining the cause of embolism, mentions bacteria and protozoa as possible causative factors. Castellani,[35] in discussing the localization of the malarial parasites, refers to the localization in many organs; he even mentions localization of the parasites in the appendix. In a necropsy mentioned by Hines[36] on a patient dying of estivo-autumnal malaria, the capillaries of the brain were found to be plugged with malarial parasites. The same condition may exist in the extremities of those affected with malaria, thus causing gangrene.

3. *Thrombosis.*—The obstruction opposed to the inflow of arterial blood may be a thrombus. There seems to be a unanimity of opinion that gangrene ensues when the arterial circulation is thus impeded. Among those holding this view are Warbasse,[37] Buerger,[4] Darier,[5] DaCosta,[12] Brusa,[2] Tyson,[31] Osler and McCrae,[38] Learmonth,[3] and Kramer.[39] According to Buerger,[4] the clotting process is apt to occur in the arteries of the extremities because of the small size of the vessels and the retardation of the blood stream; the clot may not adhere sufficiently to obliterate the artery, but usually obliteration of the artery occurs with extension of the thrombotic process toward the periphery. Goldschmidt[28] inclines to the view that there is an obliterating endarteritis. Schuster[40] and d'Arnellas[40] report cases of gangrene of the toes as due to ascending peripheral arteries caused by syphilis. Fox[41] reports a case presenting Raynaud's phenomena, viz., local syncope, local asphyxia, and gangrene, occurring in syphilitic endarteritis, which caused obliteration of the vessels. Chesky[42] considers that arterial occlusion may occur through septic or toxic endarteritis; on such a lesion a thrombus may be engrafted Many authors report the finding of thrombi on pathologic examination of amputated parts. reports a case of gangrene of the foot noted during the course of an attack of influenza; the arteries of the amputated part were found to be occluded by thrombi. Poupon,[44] in 1883, in a necropsy in a case of dry gangrene of the leg following diphtheria, found a clot 3 cm. long in the popliteal artery. In one case of gangrene in the foot following malaria, Barraud [9] noted thrombosis of the popliteal artery of the amputated part. The extent of the gangrene does not depend solely on the size and importance of the occluded artery; on the contrary, it depends on the completeness of the establishment of the collateral circulation, which is usually sufficient to reestablish the circulation in the greater part of the territory supplied by the occluded vessel.

THE CAUSE OF THROMBOSIS

A thrombus may be defined as a solid mass or plug formed in the living heart or blood vessels from constituents of the blood (Welch [32]). According to the opinion of Welch,[32] MacCallum [23] and Mason,[45] the principles concerned in thrombus formation are similar to those concerned in normal blood coagulation. Most of the theories on blood coagulation assume that in the circulating blood there is no clotting because there is no active thrombin, this substance being present in its inactive form, prothrombin. Howell's [46] theory assumes that "prothrombin can be changed to thrombin by the action of calcium alone, but that in the circulating blood this reaction is prevented by the presence of an inhibitory substance which affects the prothrombin and may, therefore, be designated in general as an antiprothrombin. The function of the tissue extract, derived from the platelets or other cells, which in this theory is believed to consist essentially of cephalin or a cephalin-protein compound, is to neutralize this inhibitory substance and liberate prothrombin so that it can be activated by the calcium." Howell [46] further states that when the internal coat of a blood vessel is injured, as for instance by a ligature, the altered endothelial cells act as a foreign substance; according to the investigations of Durante,[47] stagnant blood clots in living vessels only when their endothelium is in an abnormal condition. Weigert [47] and Zahn [47] lay especial stress on destruction of white blood corpuscles in the formation of a thrombus, and Fitz [48] states that the destruction of the red blood corpuscles is also of importance. Mason [45] assumes that the circulating blood as it passes through the normal tissues is maintained in a delicate equilibrium and that various factors, especially those substances capable of carrying an electronegative charge, are capable of disturbing this equilibrium, the most common injury being injury to the tissues. He quotes Morse [32] as calling attention to the fact that an extract prepared from the intima of the blood vessels is an active coagulant. According to the observation made by Wooldridge,[32] the stroma of the red cells when freed from hemoglobin acted as any tissue extract in accelerating blood coagulation. Aschoff,[49] in his classification of thrombi, describes one form of thrombus which is composed of the débris of red cells and other cells which may appear in quantities after some hemolytic process.

Aschoff [50] says, in connection with the subject of thrombosis, that we may "in all justice assign to infection the most important etiological rôle." He mentions that in thrombosis there is not a single cause, but many conditions which are closely related to the occurrence of thrombosis. Among these may be mentioned: "first, changes in the blood plasma (diminished or increased coagulability); secondly, changes in the blood elements (increased or diminished powers of agglutination); thirdly, changes in the blood flow (slowing and formation of eddies); and lastly, changes in the vessel wall itself (endothelial damage)." As regards the phenomena that precede thrombosis, the same author leaves unsettled the point as to whether such phenomena are of a type "long known to workers in bacteriology or serology, or whether they are chemicophysical" in nature; he further states that the agglutinability of platelets depends on the chemicophysical characters of the blood stream in which they are suspended.

According to MacCallum,[23] a thrombus begins by deposition on the walls of blood channels of a minute pearly translucent mass of platelets which grows by adhesion of other platelets as they come by; the platelets quickly catch passing leukocytes; fibrin forms and entangles red blood corpuscles. Even the final cessation of bleeding from a vessel is really due to a form of thrombosis, since the clot is produced in streaming blood.

The question as to the proximate cause of the formation of thrombi has been answered in various ways. Most of the older writers assumed a primary injury of the wall (Eberth,[49] Schimmelbusch [49] and Welch [49]), which allowed the production of the thromboplastic substance. Aschoff [50] and his colleagues contend that thrombi are essentially produced by some mechanical obstruction or slowing of the stream. MacCallum [23] says: "As a predisposing and later as a guiding factor controlling the architecture of the thrombus, modifications of the velocity and direction of the current are undoubtedly of great importance, but for the first step in the lodgment of platelets, injury to the endothelium seems to me to be of prime significance."

In considering the endothelial damage in the arterial wall in connection with the mechanism of thrombosis, it is necessary to take into consideration the relationship that exists between bacteria or their poisons and the arterial lesions, as manifested by clinical observation, postmortem findings and animal experimentation.

Frothingham [51] made a study of the aortas of thirty-six persons who died from the acute infections. Of these, twenty-one showed thickening of the intima, eleven showed fat in the intima, and four had fat in the muscle fibers of the media.

Hektoen [52] succeeded in producing endarteritis with the tubercle bacillus. The organisms, in suspension, were injected into the carotid artery of a dog, and the animal was killed about a month later. Necropsy revealed numerous minute grayish nodules in the vessels of the convexity of the brain hemisphere. Tubercle bacilli were found in these nodules, the wall of the vessel being converted into granulation tissue.

Frothingham [53] attempted to reproduce in rabbits and guinea-pigs an arterial lesion similar to that found in man. He worked with diphtheria toxin. He used rabbits and injected them with large doses. All died in from forty-eight hours to three days. Microscopic examination of the kidneys showed the glomerular tufts necrotic in places with fibrin deposit in them. The lesion was not identical with the lesion that occurs in human cases, but there was a similarity in that there was a necrosis of the vessel wall plus formation of fibrin.

Klotz[51] reports the findings in fifteen cases in which the patients died of rheumatic fever or with a history of rheumatic fever. Three patients had one attack; four, a recurrent attack, and eight, chronic rheumatism. The site of predilection in these cases he found to be in the ascending limb of the aorta. Here there was an inflammatory exudate about the vasa vasorum of the adventitia, accompanied by degenerative changes of the neighboring cells and elastic fibers.

Kretz[55] reports that in 6,511 cases he was unable to find a single instance in which thrombus formation was not associated with previous infection. Buerger[4] is more conservative. He states that necropsy material would suggest that the infectious process plays a siderable rôle in about half of the cases.

ccording to James,[56] the toxin of pernicious malaria erts a specific action on the walls of the cerebral capillaries, softening the endothelial cells and causing the infected erythrocytes to adhere to the capillary

day he had chills and fever; the following day he had fever again. Chills followed by fever continued daily until the arrival of the ship at Mobile. The day before arrival, he became delirious and his feet and legs pained him. On arrival of the ship in Mobile, on the ninth day of his illness, he was brought to the hospital by ambulance in a delirious condition. Five other patients, members of the crew of the same ship, were admitted to the hospital at the same time, all of whom, on microscopic examination of the blood, were found to have malaria; the estivo-autumnal parasite was found in two of them.

Examination.—The patient was poorly nourished and anemic. The temperature by rectum was 36 C. (96.8 F.); respiration, 32; pulse, 106, slightly irregular and of low tension. He was restless and delirious, tossing in bed; he talked incoherently. The pupils were dilated, the sclerotics pale and lemon tinted. The tongue was coated and the breath foul. The skin was clammy and pale. Moist râles were heard over both lungs, especially over the bases posteriorly. A slight systolic murmur was heard best at the apex, but was not transmitted. The heart was not enlarged. The apex beat was in the fifth interspace, 7.5 cm. from the midsternal line. The spleen was only slightly enlarged. The genito-urinary examination was negative The reflexes were normal. The extremities were cold. The toes were livid and insensitive, and showed dark blebs on the ends. Blebs were also evident on the dorsal and plantar surfaces of both feet. All toes on both feet were involved, the great toes more than the others, and the right great toe more than the left. On the inner surface of the feet near the ankles were irregular, mottled dark areas. On the plantar surface of the right foot was noted an area about

9,000; red blood cells, 4,035,000. The differential count gave: small mononuclears, 33 per cent; large mononuclears, 3 per cent; polymorphonuclears, 64 per cent. A blood smear was negative for malarial parasites. The Wassermann test of the blood was negative. The general condition of the patient was greatly improved. The heart murmur had disappeared. The right great toe showed dry gangrene, a distinct line of demarcation being present at the metatarsophalangeal joint; the plantar surface showed an area of dry gangrene approximately 5 cm. in diameter. The distal phalanx of the great toe and tip of the third toe of the left foot showed some evidence of dry gangrene. Both feet were sensitive to the touch except in the area of gangrene. The patient complained of pain and tingling in both feet.

Jan. 15, 1924, fifty-six days after admission, the right great toe was black and mummified. It was amputated at the metatarsophalangeal joint. Chemical examination of the blood showed normal findings: blood sugar, 74 mg. per hundred cubic centimeters of blood; nonprotein nitrogen, 26 mg., and urea nitrogen, 13 mg. A kidney function test, 1 cc. of phenolsulphonphthalein being given intramuscularly, showed 40 per cent excretion in two hours. The urine still showed a trace of albumin, a few red blood cells, and a few hyaline and granular casts.

February 13, eighty-four days after admission, urinalysis was negative. The albumin had completely disappeared. A

this is kept in check by the action of antihemolysin, which is formed in the body, but under certain circumstances may fail to be produced in sufficient quantity, so that hemoglobinemia with hemoglobinuria may occur. Stephens,[51] in discussing the cause of hemoglobinuria, states that until the presence of a hemolysin can be negatived by good evidence, we may adopt this as a provisional hypothesis.

The absence of pulsation in the dorsalis pedis arteries eliminates the existence of symmetrical gangrene of the Raynaud type due to vasoconstriction. Such absence of pulsation points to either embolism or thrombosis. From the facts presented, however, we may assume that thrombosis is the most probable causative factor.

The gangrene was not due to embolism associated with heart disease. There was no evidence of heart disease in this case. A slight systolic murmur heard at the apex was clearly functional.

Gangrene due to chemicals and drugs was excluded.

Traumatism was excluded as a cause of gangrene.

Syphilis was eliminated as a cause of gangrene. There was no history of syphilitic infection; the Wassermann test was negative on three different occasions. There man. He worked with diphtheria toxin. He used rabbits and injected them with large doses. All died in from forty-eight hours to three days. Microscopic examination of the kidneys showed the glomerular tufts necrotic in places with fibrin deposit in them. The lesion was not identical with the lesion that occurs in human cases, but there was a similarity in that there was a necrosis of the vessel wall plus formation of fibrin.

Klotz[54] reports the findings in fifteen cases in which the patients died of rheumatic fever or with a history of rheumatic fever. Three patients had one attack; four, a recurrent attack, and eight, chronic rheumatism. The site of predilection in these cases he found to be in the ascending limb of the aorta. Here there was an inflammatory exudate about the vasa vasorum of the adventitia, accompanied by degenerative changes of the neighboring cells and elastic fibers.

Kretz[55] reports that in 6,511 cases he was unable to find a single instance in which thrombus formation was not associated with previous infection. Buerger[4] is more conservative. He states that necropsy material would suggest that the infectious process plays a considerable rôle in about half of the cases.

According to James,[56] the toxin of pernicious malaria exerts a specific action on the walls of the cerebral capillaries, softening the endothelial cells and causing the infected erythrocytes to adhere to the capillary walls. Stephens[57] states that in "estivo-autumnal malaria fatty degeneration of the endothelium is apparently a well recognized condition in the cerebral capillaries," but he does not know how far it exists in other parts of the body. Thomson[58] says: "In the human body and also in cultures, as soon as the parasites lose their ring shape—and pigment collects—they clump in masses round the endothelial cells," and that this clumping round the endothelial cells explains their arrest in the capillaries.

REPORT OF CASE OF SYMMETRICAL GANGRENE OF FEET COMPLICATING MALARIAL FEVER

The following case is deemed worthy to report, owing to the fact that only four cases are found reported in the literature, so far as I know, in which the occurrence of symmetrical gangrene is so definitely proved to be of malarial origin:

History.—An American seaman, aged 25, single, white, admitted to the U. S. Marine Hospital, Mobile, Ala., Nov. 19, 1923, had used considerable alcohol in 1920, 1921 and 1922, but not since. He smoked moderately. The family history was negative. He had diphtheria when 8 years old, and had sustained several injuries in childhood, including a fracture of the right humerus and a burn of the left foot. There was no history of venereal disease. He had no trouble in his extremities. He never noted a smoky or bloody appearance of the urine. During the fall of 1923, he was on a voyage in the tropics. He was shipwrecked off Haiti, October 10. After forty-eight hours he was picked up and carried to Santo Domingo, where he stayed for one month. In Santo Domingo, three members of his ship were taken sick with malaria and were sent to a hospital. While in Santo Domingo, he visited the government forts several times and stated that many cases of malaria prevailed there. Eight days before admission to the hospital, he began to feel weak; the next day he had chills and fever; the following day he had fever again. Chills followed by fever continued daily until the arrival of the ship at Mobile. The day before arrival, he became delirious and his feet and legs pained him. On arrival of the ship in Mobile, on the ninth day of his illness, he was brought to the hospital by ambulance in a delirious condition. Five other patients, members of the crew of the same ship, were admitted to the hospital at the same time, all of whom, on microscopic examination of the blood, were found to have malaria; the estivo-autumnal parasite was found in two of them.

Examination.—The patient was poorly nourished and anemic. The temperature by rectum was 36 C. (96.8 F.); respiration, 32; pulse, 106, slightly irregular and of low tension. He was restless and delirious, tossing in bed; he talked incoherently. The pupils were dilated, the sclerotics pale and lemon tinted. The tongue was coated and the breath foul. The skin was clammy and pale. Moist râles were heard over both lungs, especially over the bases posteriorly. A slight systolic murmur was heard best at the apex, but was not transmitted. The heart was not enlarged. The apex beat was in the fifth interspace, 7.5 cm. from the midsternal line. The spleen was only slightly enlarged. The genito-urinary examination was negative The reflexes were normal. The extremities were cold. The toes were livid and insensitive, and showed dark blebs on the ends. Blebs were also evident on the dorsal and plantar surfaces of both feet. All toes on both feet were involved, the great toes more than the others, and the right great toe more than the left. On the inner surface of the feet near the ankles were irregular, mottled dark areas. On the plantar surface of the right foot was noted an area about 5 cm long and 5 cm. wide; this area was not raised and was of bluish discoloration. Both feet were cold to the touch, and were swollen. There was loss of pulsation in the dorsalis pedis artery, in both feet. The hemoglobin was 75 per cent; the white blood cells numbered 9,200, of which small mononuclears were 26 per cent; large mononuclears, 6 per cent, and polymorphonuclears, 58 per cent. Ring forms of the estivo-autumnal parasite were found in great numbers; a few crescents were observed. The urine was definitely smoky in appearance; the test for albumin gave a moderate ring; there was no sugar; a few epithelial cells were noted; the specific gravity was 1.020; there were a few red blood corpuscles; there were hyaline and granular casts.

Treatment.—General supportive treatment was administered; fluids were given by mouth, and moist antiseptic dressings, together with heat, were applied to the feet. Quinine dihydrochloride, 15 grains (1 Gm.), was given intravenously shortly after admission and after the diagnosis of malaria had been made; thereafter the quinine, 10 grains (0.65 Gm.), was given intravenously every six hours, for four doses. Following intravenous medication, quinine sulphate was given by mouth, 15 grains three times a day, for four days; later quinine was administered in 5-grain (0.3 Gm.) doses by mouth, three times a day.

Course.—The outstanding features of the disease, at first, were the subnormal temperature and the delirious condition of the patient. In response to the intravenous medication of quinine, the mental condition rapidly cleared. The second day after admission he complained of pain in the legs; on this day the smoky appearance of the urine disappeared; the urine was amber. The pulse gradually fell and became 90 on the fourth day after admission. The temperature rose to 38 C. (100.4 F.) on the fourth day and remained at about this level until the tenth day. This rise was thought to be due to sepsis from the gangrenous condition of the feet. The affected areas of the feet became black, and were icy cold to the touch. The blebs broke, leaving exposed surfaces. A definite line of demarcation later developed, the tissues appearing somewhat red and mottled in the area on the proximal side of the line.

December 18, thirty days after admission, the urine was acid and of amber color; there was a trace of albumin, but no sugar; the specific gravity was 1.013; there were a few red blood cells and a few hyaline and granular casts. The hemoglobin was 80 per cent; white blood cells numbered

9,000; red blood cells, 4,035,000. The differential count gave: small mononuclears, 33 per cent; large mononuclears, 3 per cent; polymorphonuclears, 64 per cent. A blood smear was negative for malarial parasites. The Wassermann test of the blood was negative. The general condition of the patient was greatly improved. The heart murmur had disappeared. The right great toe showed dry gangrene, a distinct line of demarcation being present at the metatarsophalangeal joint; the plantar surface showed an area of dry gangrene approximately 5 cm. in diameter. The distal phalanx of the great toe and tip of the third toe of the left foot showed some evidence of dry gangrene. Both feet were sensitive to the touch except in the area of gangrene. The patient complained of pain and tingling in both feet.

Jan. 15, 1924, fifty-six days after admission, the right great toe was black and mummified. It was amputated at the metatarsophalangeal joint. Chemical examination of the blood showed normal findings: blood sugar, 74 mg. per hundred cubic centimeters of blood; nonprotein nitrogen, 26 mg., and urea nitrogen, 13 mg. A kidney function test, 1 cc. of phenolsulphonphthalein being given intramuscularly, showed 40 per cent excretion in two hours. The urine still showed a trace of albumin, a few red blood cells, and a few hyaline and granular casts.

February 13, eighty-four days after admission, urinalysis was negative. The albumin had completely disappeared. A kidney function test (phenolsulphonphthalein) showed 60 per cent excretion in two hours. A Wassermann test of the blood was negative.

February 24, three months and five days after admission, the patient was discharged from the hospital in good physical condition. The feet had completely healed, except for a tingling sensation on walking.

The diagnosis was: estivo-autumnal malaria of the delirious pernicious type; symmetrical gangrene of both feet; acute nephritis, and hemoglobinuria.

COMMENT

That the disease in this instance was pernicious malarial fever is beyond question. The three pathognomonic signs of malaria as enumerated by Manson were evident: *periodicity, effect of quinine,* and the *presence of the malarial parasite.* The ring forms of the estivo-autumnal parasite were found in profusion in the red blood cells; also a few of the more mature organisms in the shape of rounded crescents.

There arises for consideration the coincident occurrence of malaria and so-called Raynaud's disease existing as separate and distinct entities. A careful history revealed the fact that there had been no prior trouble in the extremities as regards pain, blanching or cyanosis. There was no history of interrupted or intermittent paroxysms, simulating or suggesting Raynaud's disease. No members of the family were similarly affected. The patient was well and healthy until nine days before admission to the hospital, and he was pursuing a gainful occupation without pain or discomfort in his extremities or elsewhere in his body.

The occurrence of acute nephritis as a complication of malaria has not been unusual. Osler and McCrae [58] report the occurrence of acute nephritis in more than 4.5 per cent of patients suffering from estivo-autumnal fever.

The hemoglobinuria in this case was undoubtedly due to the parasite causing pernicious malarial fever. It will be noted that hemoglobinuria existed before quinine was administered, and the patient had received no quinine prior to admission to the hospital. As shown by de Blasi,[59] Brem [59] and Zeiler,[59] the malarial parasites give rise to a hemolysin which probably varies in quantity and quality with different strains of parasites; this is kept in check by the action of antihemolysin, which is formed in the body, but under certain circumstances may fail to be produced in sufficient quantity, so that hemoglobinemia with hemoglobinuria may occur. Stephens,[59] in discussing the cause of hemoglobinuria, states that until the presence of a hemolysin can be negatived by good evidence, we may adopt this as a provisional hypothesis.

The absence of pulsation in the dorsalis pedis arteries eliminates the existence of symmetrical gangrene of the Raynaud type due to vasoconstriction. Such absence of pulsation points to either embolism or thrombosis. From the facts presented, however, we may assume that thrombosis is the most probable causative factor.

The gangrene was not due to embolism associated with heart disease. There was no evidence of heart disease in this case. A slight systolic murmur heard at the apex was clearly functional.

Gangrene due to chemicals and drugs was excluded.

Traumatism was excluded as a cause of gangrene.

Syphilis was eliminated as a cause of gangrene. There was no history of syphilitic infection; the Wassermann test was negative on three different occasions. There was no adenopathy or other evidence of syphilis.

Gangrene from heat or cold was eliminated.

Senile gangrene was eliminated on physical examination and on the symmetry of the lesions.

Diabetic gangrene was eliminated on the laboratory findings. The urine was negative for sugar; examination of the blood showed blood sugar to be present in the amount of 74 mg. per hundred cubic centimeters of blood.

Thrombo-angiitis obliterans was eliminated on the history of the case, because of the absence of intermittent claudication, the absence of migrating phlebitis, the absence of a steady progressive course and the absence of redness.

Polyneuritis, as seen in beriberi, was eliminated on the history, because of the sudden occurrence of the gangrene, the absence of hyperesthesia and the presence of the patellar reflexes.

Erythromelalgia was eliminated because of the absence of bounding arterial pulsations, the absence of redness and the absence of a burning sensation in the feet.

Syringomyelia was eliminated by the onset being sudden rather than insidious, the absence of muscular atrophy, absence of sensory dissociation, and the symmetry of the lesions.

CONCLUSION

From the facts presented, this was an unquestioned case of symmetrical gangrene caused by estivo-autumnal malaria, in which unusually favorable results followed specific intravenous therapy.

Development of Psychologic Conception in Medicine.—The actual historical line of development of the pyschological conception in medicine has its roots, though hardly its logical ancestry, in the seventeenth century views and practices with regard to animal magnetism, and the personal power of healing. The ground for this statement is that, although none of these procedures were employed as the result of a psychological conception of disease or of therapy, and none of them form part of the actual building of psychopathology, yet they led to the observation of certain phenomena which were ultimately incorporated in the conception of suggestion, the conception which may be regarded as the foundation stone of modern psychopathology.—Hart, Bernard: *Lancet* **1:**587 (March 20) 1926.

[illegible] ANOMALY: FREE FIBROUS CORD [illegible] THROUGH THREE HEART [illegible] TO THE AORTA †

[illegible], M.D., PHILADELPHIA

[illegible] finding is recorded primarily [illegible] Various unusual heart abnor- [illegible] in the literature, but our search for [illegible] or like this one has been in vain; as [illegible] this anomaly is the only one of its [illegible]

[illegible] aged 23, came to necropsy with a clinical [illegible] puerperal psychosis. The history, clinical [illegible] other necropsy findings are of no consequence [illegible] According to Dr. J. F. Stauffer of the [illegible] General Hospital, on auscul[illegible] here was a [illegible] mur- [illegible] and, at the apex, a "s[illegible] [illegible] sounded like a cross betw[illegible] [illegible] was heard, which could no[illegible] [illegible] Pericarditis was [illegible] of tachycardia. The heart weighed 300 Gm; it was of [illegible] and showed slight rightsided dilatat[illegible] [illegible] and epicardium were not remarkable.

vessels were normal. The auricular and ventricular walls were of normal thickness, and the myocardium was of normal color and consistency. The endocardium and valves presented no organic lesions. The mitral valve, particularly the anterior leaflet, showed slight thickening along its line of closure, but was everywhere smooth and shining. The aortic cusps were not remarkable, except as described.

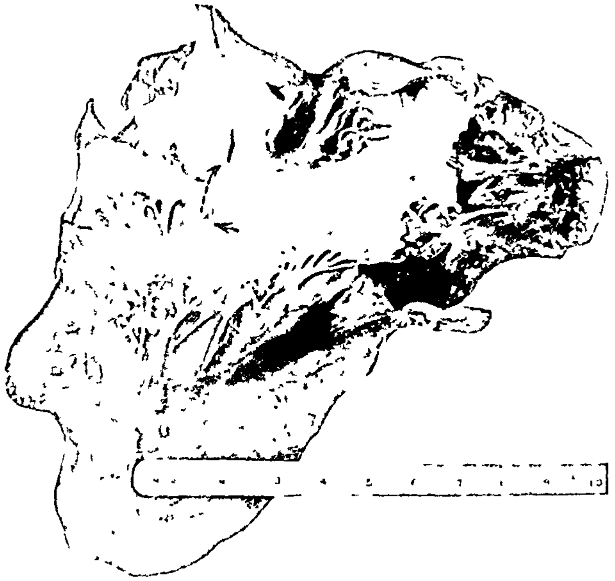

Fig. 1.—O[illegible] of cord in right auricle and its course to the annulus ovalis.

Arising from the right auricular wall 1.5 cm. from the annulus ovalis a tiny grayish-white, rounded, threadlike, smooth, glistening cord, 0.5 mm. in diameter, [illegible] freely and unattached toward the slightly patent foram[illegible] ear the

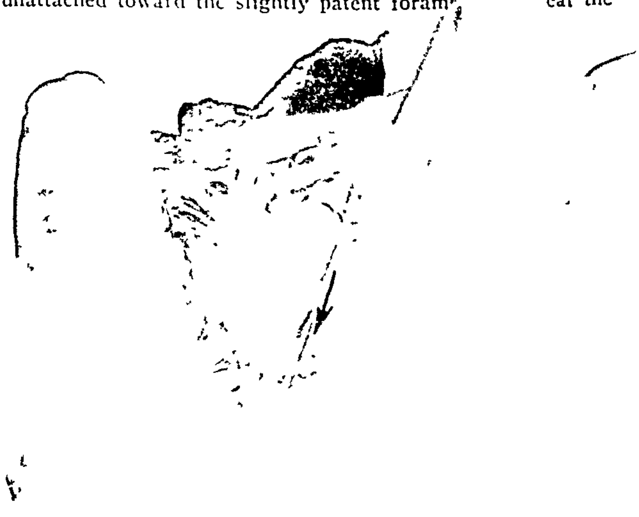

Fig. 2 [illegible] mitral [illegible] from sh[illegible] ventricle. Here it turned, and, forming a parabola-like curve around the anterior mitral leaflet, but sufficiently below it so as not to interfere greatly with its function, apparently, proceeded toward the aortic valve. As it approached the anterior cusp, it perpendicularly pierced it and attached itself to the wall of the aorta, 8 mm. beyond, thus virtually transfixing this cusp. It was as though a suture had been started in the right auricular wall and had been passed through the course of the fetal circulation, finally ending in the aortic wall, after penetrating the aortic valve. The cord tended to increase in size as it progressed: in its course through the left auricle and ventricle, it increased from 0.6 mm. to 2 mm. in diameter; it was thickest in its curve around the mitral leaflet, reaching a diameter of 2.5 mm. in this section. As it approached the aorta it again became smaller, averaging not more than 0.5 mm. as it pierced the cusp. The entire cord was about 12 cm. long; 1.5 cm. from its origin in the right auricle to the annulus ovalis; 5.5 cm. from the annulus ovalis to the curve in the left ventricle; 4 cm. from the curve to the aortic valve, and 8 mm. from the cusp to the aorta. It was rounded throughout its course, and on palpation was firm and solid, but easily pliable.

---

* From the Department of Surgery, University of [illegible]

† From the Laboratory of Morbid Anatomy of the Philad[illegible]

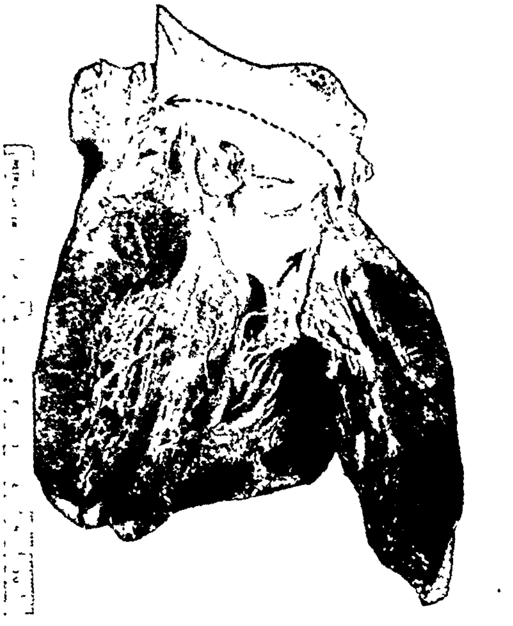

Fig. 3.—Course of cord from curve in left ventricle to aortic valve. Penetration of cusp and point of attachment on aortic wall may be noted. The cord was sectioned in the sinus of Valsalva in the routine performance of necropsy. The proximal portion can be seen in the sinus of Valsalva in the right of the illustration, and the distal portion appears as a small darkened projection near the left border of the aorta.

HISTOLOGIC STUDY

Hematoxylin and eosin, Mallory's aniline blue stain for fibrous tissue, and Weigert's elastic fiber stain preparations of both transversely and longitudinally cut sections, taken from blocks at different levels of the thickest portions of the cord, showed closely packed bundles of wavy, collagenous fibrils running longitudinally in the main, although a few took a circular course. An occasional flattened endothelial cell was observed on the outer surface. Transverse sections of the portion of the cord that had pierced the aortic cusp showed essentially the same picture; the dense fibrous tissue here tended to arrange itself in a sort of laminated fashion. Transverse sections taken through the auricular attachment of the cord showed a zone of fibrous tissue beneath the endocardium, gradually increasing in thickness as the cord was approached, and finally becoming a part of the cord. Sections through the aortic attachment showed an area of dense fibrous tissue, irregularly arranged, and apparently not intimately connected with the aortic wall tissues, beneath the endothelial coat of the intima. It appeared as though the cord had its roots in the auricular wall and was only superficially attached to the aortic wall. In no section was there any evidence of cardiac or smooth muscle tissue, elastic tissue, or Purkinje's fibers. Microscopically, then, the cord was composed of dense fibrous tissue, and was covered by a thin endothelial membrane.

COMMENT

An explanation for this anomaly is hardly possible. The points of attachment and course of the cord suggest that it might have been formed in the right auricle during fetal life in association with some irregularity in the fetal circulation, and, as a gradually lengthening process, passed through the foramen ovale and the aortic cusp before their development was complete. It would then be thought of as a fibrin-covered projection, constantly receiving more fibrin, which was slowly converted into fibrous tissue, until it became anchored in the aortic wall. Such an explanation is admittedly fantastic. There was nothing in the structure of the cord to indicate definitely its formation embryologically, yet its origin as a developmental anomaly seems the most probable. Histologic study refutes a parasitic origin of the cord, an origin that might possibly be suggested because of the superficial resemblance of the cord to a parasitic worm, grossly.

Clinically, the heart sounds were interesting. The presence of the cord in the blood stream probably served as an obstruction, however slight, to the blood flow. The looping of the cord around the anterior mitral leaflet, although redundant, may have handicapped to some degree its function, and the piercing and transfixion of the anterior aortic cusp no doubt interfered with its action. The peculiar sounds heard on auscultation may, perhaps, thus be accounted for.[1]

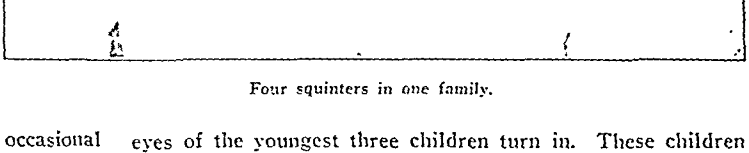
Thirty-Fourth and Pine streets.

A FAMILY OF SQUINTERS[*]

Frank H. Rodin, M.D., San Francisco

Four cases of strabismus in one family are sufficiently rare to justify this report.

Mrs. C. S., aged 46, seen at Stanford University Eye Clinic, July 14, 1925, had had fourteen children, nine of whom were living. Her right eye had always turned out. The eldest six living children and her husband have straight eyes. The eyes of the youngest three children turn in. These children were of normal birth and always healthy. The mother had always enjoyed good health. As far as can be ascertained, there is no history of strabismus on either the maternal or the paternal side of the family.



Four squinters in one family.

---

[1] In a personal communication, Dr. Maude E. Abbott states that she has never seen an anomalous cord to this extent or location in the heart. In reviewing the anomalies of the heart in Osler's Modern Medicine (4: 353-355) Dr. Abbott cites several cases showing aberrant and anomalous chordae, the nearest approach to our case being one that extended from the left auricle to the left ventricle through the mitral orifice.

Clinical Notes, Suggestions and New Instruments

STERILE PAPER TOWELS FOR SURGICAL WOUND DRESSINGS *

John Homer Woolsey, M.D., San Francisco.

Aseptic technic in the dressing of wounds is of prime importance, and is often poorly executed. For use in a surgical clinic, office or where sterile instruments and dressings are kept in bulk, the use of an "individual service sterile towel" is an excellent method. The employment of the usual linen towel is expensive, and demands considerable laundry work and renewal from the constant washing. The ordinary paper towels of rather coarse fiber are excellent and inexpensive substitutes They can be separated from one another and stacked with one corner of the closed side folded, so as to form an easy method for extraction later. The towels are then put in a hospital towel envelop and sterilized under steam pressure When they are needed, one end of the envelop is unpinned and opened, as shown in the illustration. Each sterile towel may then be withdrawn, opened, and the sterile dressings and instruments put out on the sterile field, ready for the individual patient or wound The paper towel, when used, is discarded, perhaps even with the soiled dressings folded inside.

Envelop of sterile paper towels opened ready for use

490 Post Street.

UNIQUE HEART ANOMALY: FREE FIBROUS CORD PASSING THROUGH THREE HEART CHAMBERS TO THE AORTA †

J. L. Goforth, M.D., Philadelphia

This interesting necropsy finding is recorded primarily because of its uniqueness. Various unusual heart abnormalities are described in the literature, but our search for conditions similar to or like this one has been in vain; as far as we can determine, this anomaly is the only one of its kind on record.

A white woman, aged 23, came to necropsy with a clinical diagnosis of postpuerperal psychosis. The history, clinical course, and the other necropsy findings are of no consequence and are omitted. According to Dr. J. F. Stauffer of the Philadelphia General Hospital, on auscultation there was a gallop rhythm, and, at the apex, a "sort of to-and-fro murmur which sounded like a cross between a friction rub and a murmur" was heard, which could not be definitely timed because of tachycardia. Pericarditis was suspected.

The heart weighed 300 Gm.; it was of normal size and shape, and showed slight rightsided dilatation. The pericardium and epicardium were not remarkable. The coronary vessels were normal. The auricular and ventricular walls were of normal thickness, and the myocardium was of normal color and consistency. The endocardium and valves presented no organic lesions. The mitral valve, particularly the anterior leaflet, showed slight thickening along its line of closure, but was everywhere smooth and shining. The aortic cusps were not remarkable, except as described.

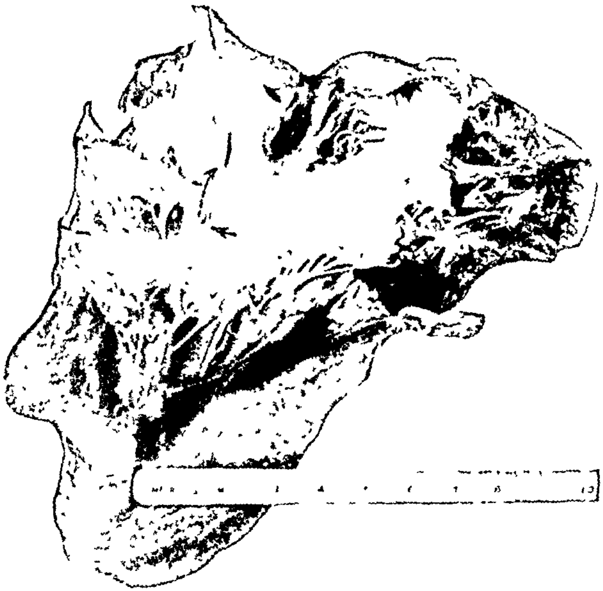

Fig 1 —Origin of cord in right auricle and its course to the annulus ovalis

Arising from the right auricular wall 1.5 cm. from the annulus ovalis, a tiny, grayish-white, rounded, threadlike, smooth, glistening cord, 0.5 mm. in diameter, ran freely and unattached toward the slightly patent foramen, and, near the lower rim of the annulus ovalis, apparently obliquely pierced the interauricular wall. Attached to the annulus ovalis, near its inferior margin in the left auricular wall, it traversed the left auricle and, following the course of the blood flow, passed down through the mitral orifice well into the left

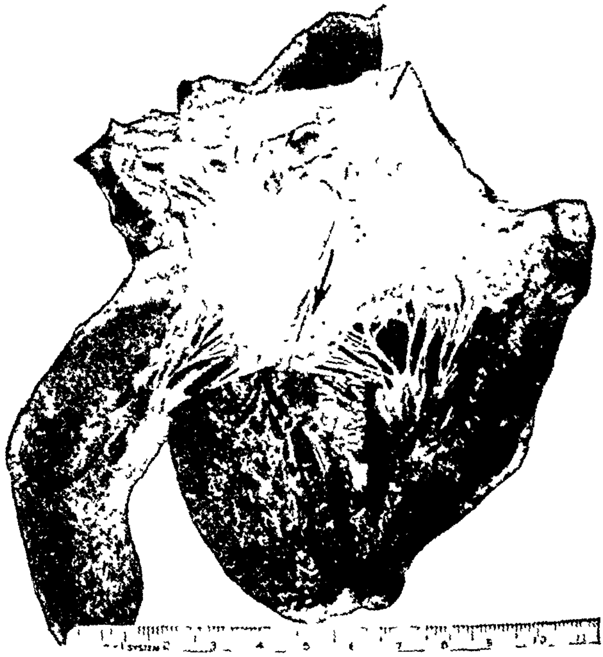

Fig 2 —Course of cord from annulus ovalis through left auricle and mitral orifice into left ventricle The cord is considerably shortened from shrinkage resulting from fixation in formaldehyde.

† From the Laboratory of Morbid Anatomy of the Philadelphia General Hospital.

ventricle. Here it turned, and, forming a parabola-like curve around the anterior mitral leaflet, but sufficiently below it so as not to interfere greatly with its function, apparently, proceeded toward the aortic valve. As it approached the anterior cusp, it perpendicularly pierced it and attached itself to the wall of the aorta, 8 mm. beyond, thus virtually transfixing this cusp. It was as though a suture had been started in the right auricular wall and had been passed through the course of the fetal circulation, finally ending in the aortic wall, after penetrating the aortic valve. The cord tended to increase in size as it progressed: in its course through the left auricle and ventricle, it increased from 0.6 mm. to 2 mm. in diameter; it was thickest in its curve around the mitral leaflet, reaching a diameter of 2.5 mm. in this section. As it approached the aorta it again became smaller, averaging not more than 0.5 mm. as it pierced the cusp. The entire cord was about 12 cm. long; 1.5 cm. from its origin in the right auricle to the annulus ovalis; 5.5 cm. from the annulus ovalis to the curve in the left ventricle; 4 cm. from the curve to the aortic valve, and 8 mm. from the cusp to the aorta. It was rounded throughout its course, and on palpation was firm and solid, but easily pliable.

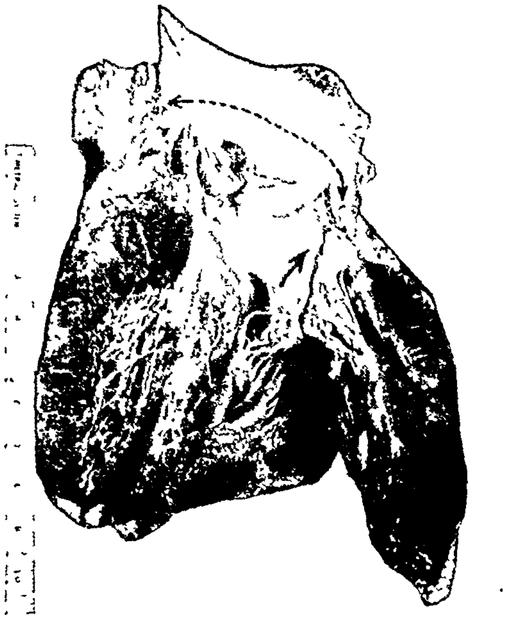

Fig. 3.—Course of cord from curve in left ventricle to aortic valve. Penetration of cusp and point of attachment on aortic wall may be noted. The cord was sectioned in the sinus of Valsalva in the routine performance of necropsy. The proximal portion can be seen in the sinus of Valsalva in the right of the illustration, and the distal portion appears as a small darkened projection near the left border of the aorta.

HISTOLOGIC STUDY

Hematoxylin and eosin, Mallory's aniline blue stain for fibrous tissue, and Weigert's elastic fiber stain preparations of both transversely and longitudinally cut sections, taken from blocks at different levels of the thickest portions of the cord, showed closely packed bundles of wavy, collagenous fibrils running longitudinally in the main, although a few took a circular course. An occasional flattened endothelial cell was observed on the outer surface. Transverse sections of the portion of the cord that had pierced the aortic cusp showed essentially the same picture; the dense fibrous tissue here tended to arrange itself in a sort of laminated fashion. Transverse sections taken through the auricular attachment of the cord showed a zone of fibrous tissue beneath the endocardium, gradually increasing in thickness as the cord was approached, and finally becoming a part of the cord. Sections through the aortic attachment showed an area of dense fibrous tissue, irregularly arranged, and apparently not intimately connected with the aortic wall tissues, beneath the endothelial coat of the intima. It appeared as though the cord had its roots in the auricular wall and was only superficially attached to the aortic wall. In no section was there any evidence of cardiac or smooth muscle tissue, elastic tissue, or Purkinje's fibers. Microscopically, then, the cord was composed of dense fibrous tissue, and was covered by a thin endothelial membrane.

COMMENT

An explanation for this anomaly is hardly possible. The points of attachment and course of the cord suggest that it might have been formed in the right auricle during fetal life in association with some irregularity in the fetal circulation, and, as a gradually lengthening process, passed through the foramen ovale and the aortic cusp before their development was complete. It would then be thought of as a fibrin-covered projection, constantly receiving more fibrin, which was slowly converted into fibrous tissue, until it became anchored in the aortic wall. Such an explanation is admittedly fantastic. There was nothing in the structure of the cord to indicate definitely its formation embryologically, yet its origin as a developmental anomaly seems the most probable. Histologic study refutes a parasitic origin of the cord, an origin that might possibly be suggested because of the superficial resemblance of the cord to a parasitic worm, grossly.

Clinically, the heart sounds were interesting. The presence of the cord in the blood stream probably served as an obstruction, however slight, to the blood flow. The looping of the cord around the anterior mitral leaflet, although redundant, may have handicapped to some degree its function, and the piercing and transfixion of the anterior aortic cusp no doubt interfered with its action. The peculiar sounds heard on auscultation may, perhaps, thus be accounted for.[1]

Thirty-Fourth and Pine streets.

A FAMILY OF SQUINTERS *

Frank H Rodin, M D., San Francisco

Four cases of strabismus in one family are sufficiently rare to justify this report.

Mrs. C. S., aged 46, seen at Stanford University Eye Clinic, July 14, 1925, had had fourteen children, nine of whom were living. Her right eye had always turned out. The eldest six living children and her husband have straight eyes. The eyes of the youngest three children turn in. These children were of normal birth and always healthy. The mother had always enjoyed good health. As far as can be ascertained, there is no history of strabismus on either the maternal or the paternal side of the family.

Four squinters in one family.

---

[1] In a personal communication, Dr. Maude E. Abbott states that she has never seen an anomalous cord to this extent or location in the heart. In reviewing the anomalies of the heart in Osler's Modern Medicine (4: 353-355) Dr. Abbott cites several cases showing aberrant and anomalous chordae, the nearest approach to our case being one that extended from the left auricle to the left ventricle through the mitral orifice.

* From the Department of Ophthalmology, Stanford University Medical School.

Retinoscopy of the mother and the children was done under atropine mydriasis. The examination of the fundi in all these cases was negative. Lenses did not improve their visions nor straighten out the eyes.

Examination of the vision of Mrs. C. S. revealed: O. D. = hand movement; O S = 20/30. Retinoscopy: O. D. + 2.00 ⊃ + 2.00 axis 90°; O. S + 2 00 S. There was a right divergent strabismus, the right internal rectus muscle being very weak.

The eldest of the three children was a boy, aged 12 years. The right eye had been turning in since 2 years of age. Vision: O D. = 20/30, O S. = 20/30 part. Retinoscopy: O. U. + 5 00 S. In a postmydriatic test, the patient accepted only O. U. + 0 75 S. There was an alternating convergent strabismus of 30 degrees by the arc test, the left eye being the fixing eye.

The second child was a girl, aged 9 years. The right eye had been turning in since 2 years of age. The right pupil was larger than the left Vision· O. D = 20/200; O S. = 20/40. Retinoscopy: O D. + 4.00 ⊃ + 1.00 axis 135°; O. S. + 4 00 ⊃ + 1 00 axis 45°. Postmydriatic test: O. D. did not accept any lens; O. S accepted + 1 00 S. By the arc test: right convergent strabismus 30°.

The youngest child was a girl, aged 6 years. The left eye had been turning in since 1 year of age. The child was too young for recording vision Retinoscopy: O U. + 5.50 S. By the arc test: left convergent strabismus 30°.

CARDIOSPASM AND CONCOMITANT ESOPHAGEAL DIVERTICULUM

John H. Fitzgibbon, M D., Portland, Ore.

As the occurrence of either cardiospasm or diverticulum of the esophagus is relatively infrequent, the existence of the two conditions in the same individual is rather unusual.

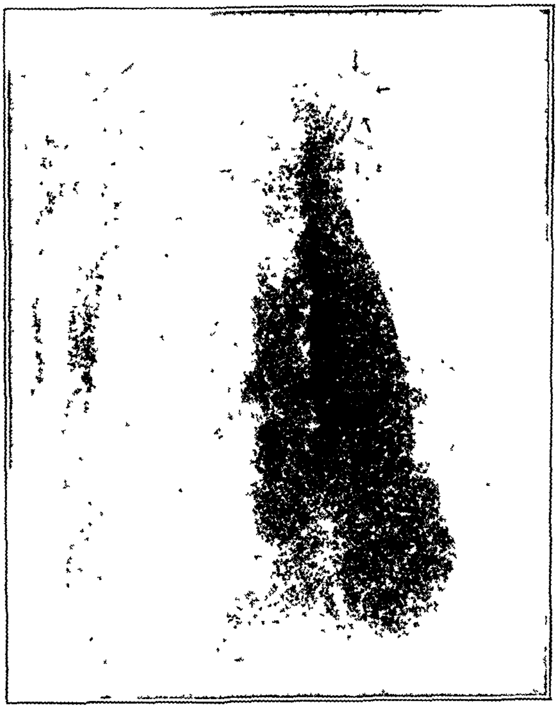

Fig. 1.—Cardiospasm and diverticulum.

Dessecker[1] states that, in eight cases of diverticulum of the lower third of the esophagus, cardiospasm was found in five; and he believes that even when it is absent, a careful history may reveal symptoms of spasm at some time. The accumulation of food in a spot weakened congenitally, or by traction from cicatrices, is thought to be a causative factor. A further contributing factor, he believes, is the negative pressure of air in the thorax as affecting that in the esophagus. Vinson[2] has reported two cases of diverticulum of the middle third of the esophagus associated with cardiospasm.

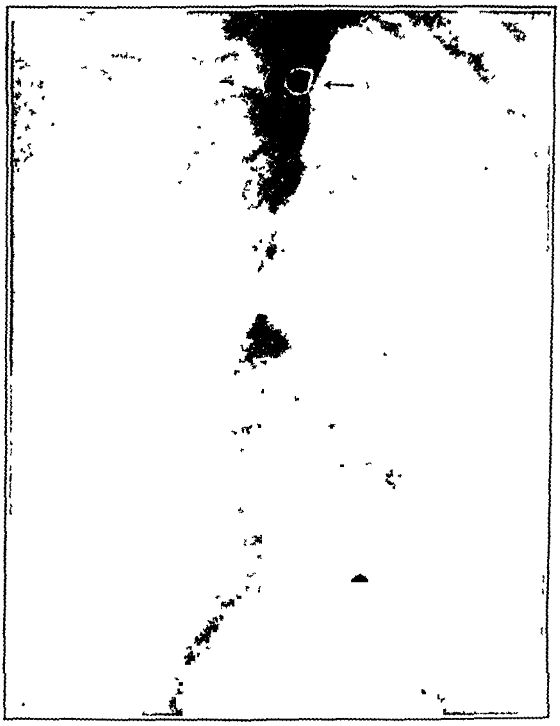

Fig. 2.—Barium residue in diverticulum.

The case here reported presents the very unusual condition of pulsion diverticulum of the upper end of the esophagus with concomitant cardiospasm.

REPORT OF CASE

O. L. C., a man, aged about 40, seen in December, 1924, had had difficulty in swallowing for fourteen years. The location of the obstruction was described as at the lower end of the esophagus. A stomach tube or esophageal bougie could be passed into the stomach with little difficulty, but the patient swallowed cold water with marked effort.

Fluoroscopic examination confirmed the diagnosis of cardiospasm, and, in addition, revealed a small diverticulum of the upper end of the esophagus, which was evidently of the pulsion type. Roentgen-ray films showed the pouch extending beyond the left border of the esophagus (fig. 1). As the esophagus emptied, a residue of barium could be seen remaining in the diverticulum (fig. 2).

All symptoms were referred to the cardiac end of the esophagus, and the diverticulum was apparently not causing difficulty. After the patient had swallowed a silk thread guide, the cardia was dilated with a Sippy air bag dilator. This was followed by marked improvement, and the patient has, so far, not reported for further treatment.

COMMENT

This case is of interest only because of the rarity of the condition, for the diverticulum is apparently too small to cause much difficulty in swallowing. In similar cases found in the literature, the diverticula have been of the middle or lower third of the esophagus.

A NEW DUODENAL TIP

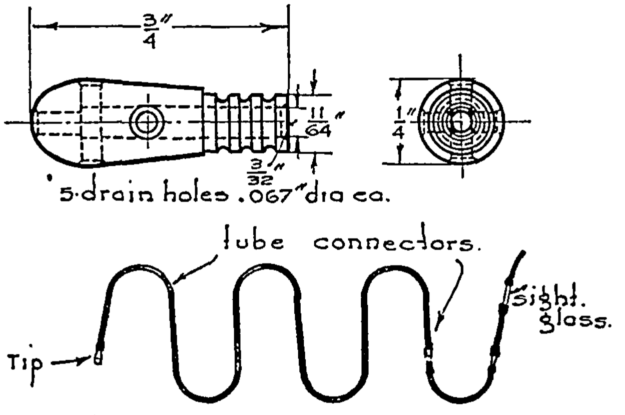
Carl V. Vischer, M.D., Philadelphia

After having used a number of the standard duodenal tubes, such as those of Jutte, Rehfuss, Lyon and Einhorn, with the aid of my brother and associate, Dr. Thomas J. Vischer, I designed a duodenal tip as shown in the accompanying illustration.

The tip is ¾ inch (2 cm.) in length, ¼ inch (0.6 cm.) in diameter, 11/64 inch at the threaded end and the caliber, 3/32 inch. There are five drain holes placed as shown in the illustration, each 0.067 inch in diameter and countersunk. The tip may be used on any standard tube. We have used the tip on both the Jutte and Rehfuss tubes. It weighs exactly 2.75 Gm.; it is made of German silver and is double gold plated.

After having constantly used the tip over a period of time, I have noted the following advantages:

1. The tube is more easily introduced; it is never necessary to use wire.
2. There is less discomfort to the patient in swallowing.
3. More rapid passage into the duodenum is obtained.
4. The tube may be introduced through the nostril.
5. There is better drainage with less obstruction by mucus.
6. Aspiration is made easier when necessary.



Above, side view and cross-section of duodenal tip; below, tip connected with tube.

The Vischer duodenal tip is manufactured by Richard Young, instrument maker, Fifteenth Street, above Race Street, Philadelphia.

5903 Greene Street, Germantown.

A NEW TIP FOR GASTRODUODENAL TUBES

Moses Einhorn, M.D., New York

I delayed the announcement of my new tip for gastroduodenal tubes in order first to convince myself that it possessed decided advantages on the tips already in use. I am now in a position to state that I have used the tip on a number of my private patients and also on patients in the dispensary of Mount Sinai Hospital, and find that it takes from one third to one half less time to enter the duodenum, as compared with other tips used on the same patients.

The tip, shown in the accompanying illustrations, is 27 French in diameter, 10/8 inches in length, of capsule shape, with an obtuse point, and has three divisions: (*a*) the top, made of nickel, through which a large opening is bored, which serves as an outlet for the drainage chamber to the tube which is attached to the neck of the capsule; (*b*) the spiral, made of round metal wire, which connects the top to the body, and by its circular arrangement offers a large drainage area; (*c*) the bottom, made of solid lead, and connected with the top by the spiral, and also by a wire which runs diagonally through the drainage chamber.

The construction of my tip is based on principles which make it ideal in gastroduodenal intubation and drainage, for the following reasons:

1. The swallowing of the tip is accelerated because of its capsular shape and its heavier weight, which is sufficient to permit the passage of the tube through the esophagus with a minimum of discomfort to the patient.

2. The tip maintains its intended course along the stomach pathway because of its weight, which is 170 grains (11 Gm.), and its proper arrangement, its distal end being made of solid lead three times heavier than the upper part, which aids it to travel along the small curvature and keeps it in proper place in its progress toward the pyloric opening.

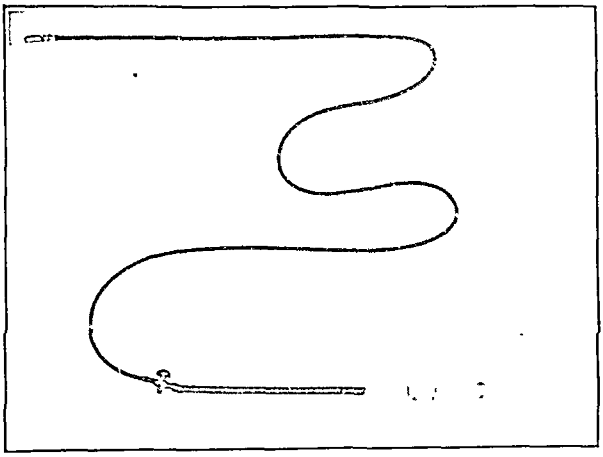


Fig. 1.—Gastroduodenal apparatus with tip in place.

3. The entrance of the tip into the doudenum is accelerated: (*a*) by placing the patient in a reclining position on the right side, with the right leg and knee stretched straight, and the left leg and knee flexed, overlapping the right, thus bringing the duodenum lower than the stomach; (*b*) by injecting a small amount of lukewarm water through the tube, which will relax the pyloric opening and stimulate the peristalsis of the stomach; (*c*) by having the patient swallow the last 7 inches (18 cm.) of the tube slowly, over a period of from ten to fifteen minutes, which assists the progress of the tip along the stomach pathway.

4. The large drainage chamber permits the extraction of pieces of mucus and juice, and also permits a continuous drainage of the tube. This is accomplished by the openings formed by the circular spiral, which promotes drainage from all sides.

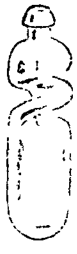

Fig 2.—Appearance of tip.

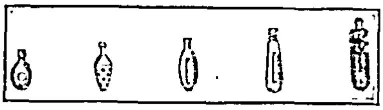
5. There is minimum injury to the mucous membrane of the stomach and duodenum, either in course of drainage or on withdrawing the tip; this is accomplished by having the spiral made of round metal wire and the upper edge of the bottom of the tip smoothly beveled.

Comparison of Tip with Others Now in Use



Length, inches	6/8	7/8	8/8	9/8	10/8
Weight, grains	104	59	83	72	170
Diameter, French	34	23	29	27	27

The tube should be of semisoft quality, to lessen the possibility of knotting and bending.

The tube is 12 French in diameter, semisoft in quality, and 50 inches (127 cm.) in length. It is divided by heavy lines, one line being placed 20 inches (50 cm.) from the tip; two lines, 27 inches (70 cm.) from the tip; and three lines, 34 inches (85 cm.) from the tip. At the end of the tube, I introduced a rubber stopcock, which is very useful, particularly after the injection of magnesium sulphate used in the course of drainage, as it does not permit of dripping, and also in fractional methods for gastric contents.

Important points to remember during the intubation are:

1. The tube should never be introduced farther than the first heavy line, which is 20 inches from the tip, before placing the patient on the right side.
2. After the drainage is completed and one is ready to remove the tube, the first seven inches should be withdrawn while the patient is still in a recumbent position; only then should the patient be placed in an upright position, while the rest of the tube is being withdrawn.

EMBRYONIC MIXED TUMOR OF THYROID *

J. Warren Bell, M D, Ph D, Everett, Wash.

Mrs. H presented herself for examination believing she was pregnant. Examination revealed a distended abdomen, in which no fetus could be palpated Catheterization of the bladder secured a few ounces of normal urine The roentgen ray revealed an hydramnios with outlines of a fetal skull visible The skull did not appear as large as a full term fetus, though the abdomen was as large as is usual at term. The patient was put to bed and the hydramnios diminished slightly, but in spite of rest and sedatives she went into labor prematurely, with a discharge of considerable amniotic fluid.

I arrived just in time to assist in extracting by the feet the fetus shown in the accompanying illustration. The child breathed spasmodically a few times and then stopped The mother had a prolonged convalescence, owing to the assumption of household duties before she was strong enough for this responsibility

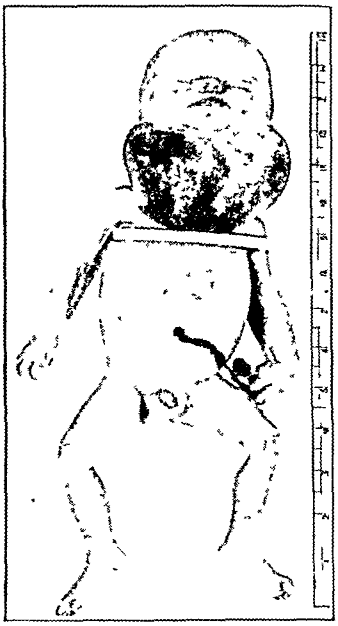

Fig 1 —Appearance of fetus, showing tumor of thyroid

A roentgenogram of the specimen showed no evidence of bone formation in the tumor.

Dissection of the abdomen and thorax showed the viscera in normal position and of normal appearance. The tumor was so large that we considered several sources of origin, but the anatomic relations proved by dissection that it was from the thyroid alone The tumor was quite firm, slightly elastic and heterogeneous in appearance on section On microscopic section the tissue would not be identified as thyroid on casual observation. The various sections differed from one another.

The first microscopic section showed a definite piece of cartilage The second microscopic section showed a tubular area, while the third section showed embryonic tissue.

DIFFERENTIAL DIAGNOSIS

When we refer to the literature we find that Hertzler[1] includes under tumors of the thyroid the following:

1. Adenoma: (*a*) fetal; (*b*) tubular.
2. Thyroid cysts.
3. Carcinoma.
4. Sarcoma: all cell types.
5. Rare tumors: (*a*) fibromas; (*b*) lipomas.

Scudder[2] pictures a series of tumors which bear some resemblance to the gross appearance of the tumor in our case. They are lymphangiosarcoma (unilateral aspect), periosteal osteosarcoma of lower jaw (unilateral), large fibroma, osteofibroma, dentigerous cyst, adamantine epithelioma, and carcinoma.

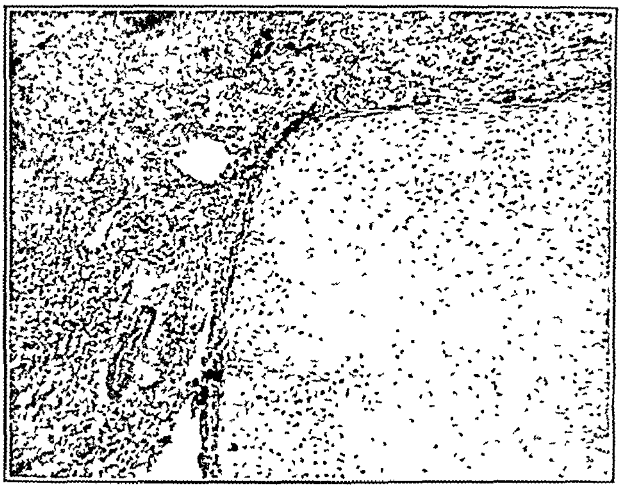

Fig 2 —Microscopic section showing area of cartilage.

Gaylord and Marsh,[3] in their work with salmonoid fishes, picture massive tumors in trout, of gross appearance similar to our tumor. The microscopic appearance of such tumors shows considerable variation.

Gardner[4] gives us a picture of a teratoma (always congenital) of the thyroid and also of a multiple cystic lymphangioma (usually congenital).

In our case, exact diagnosis is impossible except by careful microscopic examination, since the roentgen ray revealed no bony elements in the tumor Because of the size of the growth and the feebleness of the child, this tumor could not have been successfully removed.

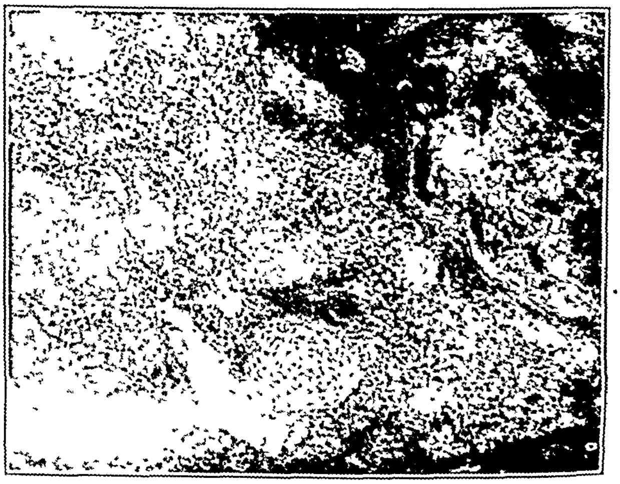

Fig 3 —Microscopic section showing embryonic tissue

RELIGIOUS HEALING

PRELIMINARY REPORT

ALICE E. PAULSEN, Ph.D.
NEW YORK

(Continued from page 1524)

SCIENTIFIC CHRISTIANITY

Christianity to some is distinctly a healing movement. Applied Christianity, they believe, is capable of removing every difficulty in the world. Especially is it applicable to physical disease. Christ preached faith, and those who apply the Gospel teachings to the healing of the body lay stress on this mental state. They have developed systems by which the patient's mind becomes imbued with the idea that by communion with God he may be healed, and also teach methods by which this communion may be effected. The material used to develop these ideas is taken from the Scriptures and from the writings of various New Thought authors. The system usually consists of daily reading along these lines, meditation on certain appropriate thoughts, relaxation and affirmative prayer. Treatment consists of relaxation, reading or listening to an appropriate passage of Scripture, affirmation or silent prayer.

The most highly organized movement of this nature is Unity, Scientific Christianity. Kansas City is the headquarters for this movement. It publishes a magazine called *Unity*, which has a circulation of about 185,000. This contains news of interest to the various centers, which are established throughout the country in the form of prayer groups, discussions of the teachings of the gospels as interpreted by the leaders of the movement, testimonials of results obtained by various members through the application of their principles, and other matter. Lecturers are sent out from headquarters to organize guilds in communities, and a prayer service is maintained at the larger centers. It is said that through its literature, lecturers, guilds, practitioners and prayer service the Unity Society reaches from three to five million people yearly.

The following testimonials, quoted from recent issues of *Unity*, indicate the type of response to the prayer service provided at the Kansas City headquarters:

HEALTH

Peoria, Ill.—I am thankful to you for the healing of my son. His arm was suddenly and completely healed. He did not know that I had written to you for help.—Mrs. W. C. H.

Cleveland, Ohio.—I wrote you asking that I might be healed of diabetes and gallstones. I am thankful to say that I have been healed.—Mrs. M. B.

Lorraine, Kan.—Our daughter has had an operation and the doctors said that she could not live. I asked Jesus to heal her, and I sent a telegram to *Unity*. She began to improve immediately. The doctor said that her recovery was a miracle. I thank God that she is alive and well today.—Mrs. W. E. B.

PROSPERITY

Kansas City, Mo.—I wrote you asking for prayers to assist me in renting vacant apartments. Each day I faithfully held the thought that you sent me and all the apartments now are filled.—A. L. M.

East Orange, N. J.—I have made a business connection which has promise far beyond any hopes that I entertained when I wrote you for prayers. May God bless you in your wonderful work.—C. F. B.

New York.—Wonderful things have happened since I wrote to you. I was then out of work. Now I am in my old position, and have had a raise in salary.—M. T.

MISCELLANEOUS

Hot Springs, Ark.—Find enclosed $50, my tithe. Your literature has helped me more than I can possibly express. There was a dreadful hailstorm here and my car happened to be sitting out in the front yard. Lumps of ice larger than a hen's egg fell thick and fast. I placed everything of mine in the Lord's hands. None of my property was damaged, while all around there were battered roofs, broken windows and damaged cars. I did not forget to thank God for his protection.—Mrs. A. W. C.

Tithing is the method of reimbursement used. In a booklet published by the Unity Society entitled "Tithing," an interesting history of this method is given from the time of its appearance in the Mosaic law. From the earliest times it has been the custom for those who observe tithing to give 10 per cent of their possessions to the Lord, and it is a matter of common belief that those who do this will prosper.

The eastern representative of the Unity Society is Mr. Richard Lynch. Mr. Lynch was himself an invalid for the greater part of his life until he discovered how to heal through applying the methods which he now teaches. He talks to large audiences almost daily. The topics of his lectures include such subjects as health, happiness, prosperity, character formation and personality. Mr. Lynch also carries on some private practice in healing, and conducts services attended by an enthusiastic following on Sunday mornings. At the registered class lectures, Mr. Lynch's audience usually numbers from 300 to 500 people. He started in New York with only six people, three years ago. There are ten registered practitioners connected with the New York headquarters, and an emergency prayer service is also maintained there. Followers of this school, after a short experience with the success of its methods, prefer them to those of medicine, and voluntarily dispense with the latter in order to strengthen their faith. But Unity practitioners, like all New Thought practitioners, do not demand that they do so, and do not withdraw their services if the patient wishes to consult a physician as well.

VARIOUS OTHER SIMILAR MOVEMENTS

New Thought and Christian Science are types of the same idea expressed in somewhat different ways, though by methods fundamentally similar, however different they may be in detail. Christian Science represents what is known as an "absolute" system, while most New Thought movements represent a comparatively "relative" system. There appear to be innumerable other systems more or less like the one or the other in that they are more "relative" or "absolute" in nature. They differ in their method of treatment, some treating "silently," some "audibly," some making their appeal through excitation, others through relaxation.

One of the most extensive movements using excitation and audible treatment is the Rawson school, founded by the late F. S. Rawson in 1919. His work is being carried on by more than a hundred practitioners in this country, who treat for success, happiness and health by a system consisting of vehement negation of the undesirable and affirmation of the desired. By attuning his mind in this way, the individual is enabled to "manifest" and to "demonstrate." It is said by Rawson followers to be the highest system of thought, and they are enthusiastic in their declarations as to its practicability.

In the philosophy of Burnell, we have a system of absolute thought. The follower of this system of philosophy and thought meditates on such axioms as these:

> I know that I am because I cannot say I am not. Therefore Being or Is-ness, or Consciousness, or Self, must be Truth.
>
> Truth is that which Is, and as there cannot be that which is not, therefore that which is, or Truth, must be all there is.

The individual becomes conscious of truth, perfection, cosmic consciousness. His mind, comprehending perfection, reflects perfection; and, even as his mind, his body becomes perfect.

SPIRITUALISTS

The spiritualist movement has a firm hold in New York. There are said to be many smaller circles which meet in private homes and there are at least twenty comparatively well organized societies whose services are advertised in the Sunday newspapers as open to the public. Attendance appears to vary from about fifteen to 100 people, depending on circumstances. Healing is frequently a part of the services, and some of the church "pastors" give private consultations.

It is believed that sickness is due to demoniacal possession, and the purpose of the healing service is to drive out the evil spirit. This can be accomplished in various ways.

The individual himself may so conduct his life that the evil spirit will of its own accord depart, since all evil spirits succumb when faced in the name of Christ. Or a group of individuals, gathered to worship the greatest spirit, God, may thus invite beneficent spirits, who will overcome the evil spirit and cause him to depart.

Another method consists in availing oneself of the services of a medium, who, being guided by the spirits of certain departed ones who were authorities on this earth, goes into a trance during which he or she lends his or her body to these spirits that they may speak to the patient and advise him what to do.

Still another method is that used by Titus Bull, M.D., a colleague of the late Professor Hyslop, who believes that it is possible to demonstrate that certain types of insanity are due to the presence of evil spirits. Dr. Bull is using a medium in his practice. His method is to transfer the evil spirit from the patient to the medium and to educate it by persuasion. This is accomplished through long conversations, sometimes taking the form of serious debates. The doctor is guided in his work by the spirits of a group of famous scientists. He is thoroughly convinced that exorcising a demon results only in passing it on, and has therefore followed the educational method in his practice, for by educating the evil spirit his influence for evil may be overcome once and for all.

Exorcising is a more common method. I witnessed a series of healing services at a certain negro church in which this method was used amid considerable emotional demonstration. It consists of performing certain mesmeric passes in order to gain control over the spirit, and then commanding it to depart.

It is considered necessary for those who would be successful healers to live lives of great self denial and saintliness in order that they may command evil spirits and that these spirits may have no power over them. The patient also must take heed to his morals in order that he may be completely cured and remain well. He must make himself an unsuitable host for an evil spirit.

If a person is sufficiently saintly, it is believed that evil spirits vanish at his approach, and he may effect instantaneous cures in some cases by merely touching the sufferer. Dr. Bull states that he is forced to make all sorts of sacrifices in order to maintain his power. He also states that he is able to cure certain conditions by placing his hands on the patient. However, he is using the medium and taking notes on the exact details of the procedure in most instances in order to perfect the method for the use of others who may wish to use it and to obtain recorded data on which he hopes to base proof of his contentions.

THEOSOPHY

Certain forms of Theosophy include healing in their services. The method may be that of the spiritualists or it may make use of telepathy. In the latter case, it is believed that the patient is helped by the concentration of the thought of all those present. Each attempts to realize health for him. The patient himself assumes a rather passive attitude and believes himself to be the recipient of power thus directed to him.

Neither Theosophy nor Spiritualism, however, deals with health primarily, nor are these societies definitely organized in any way for that express purpose. Nevertheless, many of their members believe that they are benefited through such healing services, and seek such help from their leader or fellow members when they are ill. Compensation is on the basis of free will offering as a rule, although among the spiritualists there is a minimum charge of fifty cents in some cases.

This completes the discussion of organized movements independent of the church. There is yet to be considered the work of certain scattered individuals who are applying religion to the readjustment of unfortunates of one type or another who come to them for help. Some of these are individuals who believe that they have themselves been cured through faith. Many of them state that they were invalids or maladjusted in some way until religion became a unifying influence in their lives. Some have long medical histories, and not a few were definitely given up as incurable by their physicians.

By chance or through the influence of another they have succeeded in curing themselves. Their system consists of close study of the teachings of Jesus, an attempt to realize completely the import of his message, and an effort to live a truly Christian life, with all that it implies. With this realization comes a certain release from strain and a willingness to cast one's burdens on Jesus. Earnest prayer enters into the treatment of self or of others. Service for others, with its attendant joys, comes as a natural consequence of the deeper realization of truth. Prayer or relaxation accompanied by dwelling on certain ideas that tend to deepen the patient's faith and expectancy of relief act as "spiritual anesthetics." Under its influence, pain and other symptoms are said to disappear.

Another type of individual work is that carried on by the Rev. Thomas Calvert.[9] Formerly a clergyman in a parish near Albany, he has for the last fifteen years been carrying on a church mission of healing in New York. Mr. Calvert places great faith in what he terms psychanalysis, in which he says he has instructed himself since its first appearance and he uses it regularly to uncover his patients' "complexes." By persuasion and suggestion he then proceeds to reeducate the individual, using religion as a basis for the readjustment. When medical attention is required the patient is referred to a physician. Mr. Calvert is entirely willing to work with physicians, and states that his work is not in any way designed to take the place of medical attention when this is needed. The mission is supported by donations and by the fees from patients. Originally, the plan of free will offering was followed. It is still followed if the patient is not able to meet the fixed charge; but since a less systematic method of meeting expenses was found to threaten the support of the work, a definite price of $5 for forty-five minutes, $10 for ninety minutes and $15 for 120 minutes has been set. Mr. Calvert alone carries on the treatment and devotes his entire time to the work. He has many testimonials to the success of his endeavors.

---

[9] Mr. Calvert died in April, 1926.

Still another method is that pursued by John D. Quackenbos, M.D., fellow of the Academy of Medicine and professor emeritus of Columbia University. He states that he has treated in the course of his practice more than 20,000 cases of addiction to alcohol, tobacco or drugs. The method pursued by Dr. Quackenbos is to induce a subjective mental state through the administration of certain drugs, including trional, passion flower and bromide. While the patient is in that state he suggests the elimination of the pernicious habit. Dr. Quackenbos feels that when the patient is in the particular state which his medication induces, the operator has direct access to what may be the spirit, or some mental mechanism which is peculiarly susceptible to religious suggestion. He is brought to this conclusion because of the nature of the rapport established, the ready response on the part of the patient to influence for good, and the tendency to definite rejection of evil suggestions. For this reason he uses Biblical and other religious material in the suggestions which he introduces into the mind during his treatments. As a rule, these consume two hours.

Although he confines his practice mainly to the treatment of pernicious habits, he has also treated other conditions, and in cases of paralysis of one sort or another, for instance, where medicine is of little avail, he has witnessed, he believes, a marked improvement in control, securing in one treatment what it would ordinarily take weeks of reeducation in the waking state to accomplish. So potent, says Dr. Quackenbos, is an idea introduced into the mind while in this condition, that even the effects of the comparatively large doses of the drugs appear to be entirely removed by posthypnotic suggestion, and the patient experiences no difficulty in going about his regular pursuits as soon as he is brought back to consciousness.

Similar to the work of Dr. Quackenbos, but different in that the state of lowered psychologic tension may not be as profound and is brought about without drugs, is the work of certain other individuals outside the medical profession who, like the New Thought teachers, usually give public lectures, which they follow up with private courses and individual treatments. These individuals usually call themselves Practical Psychologists, or Teachers of Metaphysical Healing.

SPECIAL APPLICATIONS OF RELIGION

Included in the testimony is the work of institutions where religion is made an essential element in the reconstruction of the lives of certain individuals.

The late William Gould, who founded Gould Farm, is said to have based his entire system on the healing power of religion. Mr. Gould believed that there is a definite technic by which the spirit may be developed, and with its development physical healing follows as a natural consequence. Religious discussions, prayer and service for others enter essentially into the routine at Gould Farm. Since Mr. Gould's death, his co-workers feel that there has been a deepening of the spiritual life among them which has enabled them to carry on successfully in spite of Mr. Gould's physical absence.

Deaconess Young reports that her work with wayward girls is made possible by the influence of deep religious conviction in her own life, and uses religion as a stabilizing influence in the readjustment of those who come under her care.

The Salvation Army and other rescue societies provide testimony as to the influence of religion in the conversion of all sorts of derelicts, including the alcoholic and the drug addict.

OTHER ASPECTS OF THE SITUATION

Besides teachers and practitioners concerned in the organized movements and the individual work referred to in the preceding sections, there are many others in the field, who reach the public through magazines and books, correspondence courses, phonograph records and even radio talks.

Though we have made only a very cursory survey of the magazine field, our collection includes some twenty-five or thirty magazines with such titles as "Now," "Truth," "Leaves of Healing," etc. Brentano recently had a special display of books on this subject containing works by a hundred or more authors.

One need but consult the advertisements in the Sunday newspapers to gather some idea of the activity going on every day. There are sometimes as many as twenty or twenty-five healing services or lectures on religious healing advertised among the notices of religious services in any one of the Saturday or Sunday issues of the newspapers. Advertisements in such publications as the *Psychology Magazine* shed further light on the extent and variety of the work.

In an attempt to obtain material in the way of advertisement, dodgers, advertising lectures, etc., I have collected enough to fill more than three large scrapbooks of fifty pages each, and this material merely begins to cover the field.

MODERN MOVEMENTS WITHIN THE CHURCH

Jesus made healing a definite part of his ministry,[10] and in the Christian Church healing has been carried on more or less throughout its history. However, the attempt to introduce healing systems as a fundamental part of the Christian ministry is a comparatively recent development. There is now, however, a keen interest in this field and it is rapidly gaining ground. Especially in the Episcopal Church do we find a systematized effort to develop this work.

EPISCOPAL CHURCH

Emmanuel Movement.—The Emmanuel movement was established in the Emmanuel Church of Boston some twenty years ago by Rev. Dr. Elwood Worcester and Rev. Dr. Samuel McComb. Neither had had medical training, but both were thoroughly grounded in psychology. The Emmanuel Church is still carrying on the work, and at one time it had associated with it men of high standing in the medical profession. Dr. Richard Cabot especially appears to have been interested in this work. When Mr. Worcester and Mr. McComb started their work, it was with a desire to do something for the physical relief as well as for the moral uplift of needy people who came within their reach. The work started with a tuberculosis class in which instruction was given to sufferers from that disease who lived in the tenements and who were unable to go away for treatment. They were given general health information and instruction on methods designed to help their condition and to prevent the spread of the disease to others.

---

[10] Tabulation of the miracles of Jesus is given by Witherill, F. M.: Healing in the Churches, New York, Fleming H. Revell Company, 1925, p. 36.

The scope of the work was broadened by the addition of an "Emmanuel health class," in which treatment by suggestion was a feature. No person was admitted to the class without competent diagnosis of the case by a regular physician indicating that there was no organic disease demanding medical or surgical treatment and that the case was one amenable to treatment by psychic methods. Morning and evening clinics were held, and a weekly meeting. The daily treatments were given in the church. At the weekly meetings, the service consisted of Scripture reading, prayer and a short address. Topics such as worry, anger, habit, suggestion, insomnia, nervousness, peace in the home, what the will can do, and what prayer can do were discussed. The work of the Emmanuel clinic is now largely confined to drug and alcohol addicts. Medical supervision is not now as well provided for as formerly.

Dr. Richard Cabot made a study of 178 cases treated at the Emmanuel clinic and reports as follows: In eighty-two cases of neurasthenia, seventeen patients were much improved, sixteen slightly improved, seventeen not at all improved, and in twenty results were not reported. Of twenty-two alcoholic addicts, eight were much improved. In other cases of fears, fixed ideas, obsessions and hysteria, about one fourth of the patients showed real improvement. There was also an encouraging success in the treatment of those addicted to the use of drugs, morphine, cocaine and the like. Sad, discouraged, in some cases suicidal patients were helped and put in the way of living honorable and useful lives.

Nazarene Movement.—This movement was established by Rev. Henry Blauvelt Wilson of Boonton, N. J., in 1909. Mr. Wilson had formerly been priest in charge of Holy Cross Mission in the Ridgwood section of Brooklyn. In the course of his work he was frequently called on to comfort his parishioners and others in the hospital and in their homes when they were sick. He seemed to be particularly successful in accomplishing this and he felt that the Gospel message which he brought to them played an important rôle in the recovery of those whom he visited during their illnesses. On account of ill health on his own part he was forced to give up his work in the city and retire to a smaller parish out of town This he did and shortly afterward he established the Society of the Nazarene on the following principles:

> The Society of the Nazarene, founded on the belief in our Lord's continued interest in the health of the body as well as the salvation of the soul: requirements for membership.
>
> 1. Belief in the divinity of Jesus Christ.
> 2. Belief in the possibility of following his precepts.
> 3. Belief in his works of healing and in the perpetuation of their power among believers by the use of the sacred name "Jesus of Nazareth."

The original membership was seven persons, all directly connected with Mr. Wilson's family. Mr. Wilson has since died and the work is being carried on by Rev. A. J. Gaynor Banks, with headquarters at the House of the Nazarene, Mountain Lakes, N. J. Membership in the society now numbers about 7,000. Its official organ, the *Healing Evangel,* has a circulation of about 6,000. At the Mountain Lakes headquarters is a "guest house where approved cases are received for special care and treatment under spiritual and medical supervision,[11] a chapel where daily services are held for intercession and healing, and a training school where leaders may receive proper instruction in the work of healing, develop such gifts as they may have, and receive spiritual instruction and encouragement."

Healing is accomplished through establishing faith that Christ still heals as he did when he was on earth, and that if his help is sought in the right way it will be given. Certain healers are said to be endowed with a "gift" of healing. Some are born with it; others report having become aware of being in possession of it after some such experience as the disciples had on the day of Pentecost, after which their spiritual powers were markedly increased. Mr. Banks does not feel that he has been endowed with this gift of healing, but that he secures his results through the faith which he establishes in his patients. He believes that this state of consciousness results either in the removal of inhibitions to the natural healing forces or the stimulation of those forces, or that the body is thus conditioned to receive added strength from an infinite source. In individual cases he establishes faith through persuasion in personal conferences with the patient, teaching from those parts of the Gospel which deal with healing, and heterosuggestion with Biblical material and affirmative prayer. He has also worked up a quantity of religious material for the patient to use after the method advised by Coué; that is, by systematic autosuggestion before going to sleep, immediately on waking, and at intervals during the day.

The activities of the director of the Nazarene movement include missions, individual treatments and intercessory prayer. A prayer service for others is held daily for those who ask for prayer to help them in any difficulty. The director includes in his prayers the names of all those who have communicated their need to him in person or by letter, telegraph or other means.

Missions are held in various parts of the country by invitation from the clergy of the district. Previous to the coming of the missioner, the people are prepared through sermons to come to the mission expecting physical or spiritual help. The latter is considered as important as, if not more important than, the former; for although instantaneous or gradual physical cures are reported, it is believed that in the majority of cases the spiritual cure, that is, the enhancement of the patient's faith, desire to live a godly life or ability to make the best of his handicaps if they cannot be removed, is the most important contribution of this work. It is stated that very often the patient's entire outlook on life is changed for the better, although his physical condition may remain the same

---

[11] There is a resident nurse on the guest house staff, but no physician. Presumably medical cases are under the care of their own or local physicians. Plans for the future development of the work include more adequate provision for medical supervision.

A mission lasts for several days. Healing services and individual conferences are held daily. Any one who is ill or in trouble of any kind is welcomed and no one is excluded. No diagnosis in the case of physical conditions is required, nor has there been any systematized follow-up of the results. It is, however, definitely understood that the healing services are not intended to interfere with medical attention.

The services are similar to an ordinary church service, with sermon, hymns and prayers designed to increase expectancy. Following the services, all those who wish to do so may go forward to receive the missioner's blessing, laying on of hands, and anointing with oil.

These missions are attended by hundreds, sometimes thousands, and by people suffering from all sorts of disease, as well as by those who attend merely for the spiritual uplift thus obtained. Interest in this type of service was greatly increased by the world-wide tour of the Divine healer Hickson, who has just completed a tour of the world under the auspices of the Episcopal Church, and Hickson's methods are being followed rather closely in the work of the Nazarene movement. As the healer anoints the petitioner he addresses him in a positive manner, telling him that he will be healed, and that from henceforth he must obey God's laws, that he cannot expect to be healed and continue in godless ways, and that he shall repent and begin anew at once.

After the mission has been held in a community, a prayer guild is established there to continue with the work. The nucleus is made up of those whose interest has been kindled by the mission. Regular meetings are held at which prayers are said for the members and for others who may ask to be helped by the prayers. Such a prayer guild, probably the best established of its kind in New York, has been in existence for the last seven years in Grace Church. It is reported to have accomplished many seemingly miraculous cures as well as to have justified its continuation through its influence on the general spiritual welfare of its members.

The work of the Nazarene movement is supported by membership dues, subscription to the monthly magazine, sale of other literature dealing with the work, free will offering for benefits received, and other voluntary contributions. Its purpose is not to take the place of other religious activity, but to make healing through faith a part of the work of the church. Nor is it designed to take the place of medicine, but to offer an aid to medicine. On the other hand, there is a tendency on the part of the leaders of the movement to believe that, with proper technic and development of the spiritual nature, more material methods may in time be superseded.

Church Mystical Union.—The purpose of this movement is to advance mysticism in the church. It attempts to cultivate the soul after the methods of the mystics. The movement is well established in England and is now gaining a following in this country. Rev. L. W. Fearn, warden of the Church Mystical Union, is at present engaged in the advancement of the movement in the United States. He holds services in certain churches, lectures on religious subjects, and gives private consultations.

Mr. Fearn states that in England he carries on work in cooperation with physicians, and says that he has been able to assist in the cure of many supposedly incurable conditions. He is loath to discuss this part of his work, however, since he believes it is only a corollary to his main purpose, which is to develop the spiritual nature. He believes that this can be accomplished by a definite technic, including righteous living and certain mystical influences. When the spiritual side of his nature is developed, the individual becomes conscious of latent power of which he was formerly quite unaware, and his entire attitude toward life is changed. "Superconsciousness," or "cosmic consciousness," with its attendant expansive influence, is the end in view.

Mr. Fearn states that he has so developed certain latent powers within himself that he is able to diagnose a patient's physical condition by placing his hands on him. He is also able to discern the relative degree of potential spirituality present in a given individual merely by being in his presence for a short time. His treatment begins at the level at which he finds the patient, and is in accordance with the spiritual potentiality of the individual.

Individual Efforts.—(*a*) Group Treatment: Certain churches since the time of Hickson's campaign have continued to hold weekly healing services. Chief among them are St. Luke's, Trinity Chapel, Church of the Transfiguration and St. Mary's Episcopal Church. The attendance at these services varies, and the leaders are inclined to believe that the group method should be replaced by more individualized work. In the healing service, prayer and laying on of hands preceded by a short sermon is the usual procedure.

(*b*) Personal Treatment. 1. Primarily for physical healing. Certain clergymen who have been especially interested in the subject of healing have developed a technic for individual work. This consists for the most part in allowing the patient to talk about his difficulties, convincing him of Christ's power to heal, prayer, and in some cases laying on of hands. If the case is carried over a long period of time, instruction along the lines of Christian living is given. Rev. William T. Walsh of St. Luke's Church, who has perhaps given more thought to this subject than any one else not exclusively engaged in the practice of healing, states that there is in the Bible abundant evidence of a very definite technic of healing used by Jesus and his disciples. His forthcoming book[12] will discuss this subject.

"In dealing with the individual patient," says Mr. Walsh, "the best results are obtained when the patient is in a subjective state. When a subjective state has been brought about, emphatic, positive suggestion must be given."

It is necessary for the one giving the treatment "to be quietly but deeply aware that life in him and life in the patient are one manifestation of the ultimate reality in the universe, namely, spirit." By spirit Mr. Walsh means "a reality which is not material, such as life." "When a person is sick, something has gone wrong with the 'life.'" He believes that it is just as possible to transfuse this "nonmaterial reality" as it is to transfuse a "material reality" like blood. The technic by which the one is accomplished must be just as carefully developed as the other.

Mr. Walsh describes a healing treatment as follows:

SPIRITUAL HEALING IN THE CRISIS OF A DISEASE

A lawyer was stricken by a severe attack of pneumonia. In due course came the crisis, and while it was pending his wife sent for me.

On arriving at their home, I asked, "What does the physician say?" The answer showed that it was a typical case.

Mr. Fearn states that he has so developed certain latent powers within himself that he is able to diagnose a patient's physical condition by placing his hands on him. He is also able to discern the relative degree of potential sprituality present in a given individual merely by being in his presence for a short time. His treatment begins at the level at which he finds the patient, and is in accordance with the spiritual potentiality of the individual.

Individual Efforts.—(*a*) Group Treatment: Certain churches since the time of Hickson's campaign have continued to hold weekly healing services. Chief among them are St. Luke's, Trinity Chapel, Church of the Transfiguration and St. Mary's Episcopal Church. The attendance at these services varies, and the leaders are inclined to believe that the group method should be replaced by more individualized work. In the healing service, prayer and laying on of hands preceded by a short sermon is the usual procedure.

(*b*) Personal Treatment: 1. Primarily for physical healing. Certain clergymen who have been especially interested in the subject of healing have developed a technic for individual work. This consists for the most part in allowing the patient to talk about his difficulties, convincing him of Christ's power to heal, prayer, and in some cases laying on of hands. If the case is carried over a long period of time, instruction along the lines of Christian living is given. Rev. William T. Walsh of St. Luke's Church, who has perhaps given more thought to this subject than any one else not exclusively engaged in the practice of healing, states that there is in the Bible abundant evidence of a very definite technic of healing used by Jesus and his disciples. His forthcoming book[12] will discuss this subject.

"In dealing with the individual patient," says Mr. Walsh, "the best results are obtained when the patient is in a subjective state. When a subjective state has been brought about, emphatic, positive suggestion must be given."

It is necessary for the one giving the treatment "to be quietly but deeply aware that life in him and life in the patient are one manifestation of the ultimate reality in the universe; namely, spirit." By spirit Mr. Walsh means "a reality which is not material, such as life." "When a person is sick, something has gone wrong with the 'life.'" He believes that it is just as possible to transfuse this "nonmaterial reality" as it is to transfuse a "material reality" like blood. The technic by which the one is accomplished must be just as carefully developed as the other.

Mr. Walsh describes a healing treatment as follows:

SPIRITUAL HEALING IN THE CRISIS OF A DISEASE

A lawyer was stricken by a severe attack of pneumonia. In due course came the crisis, and while it was pending his wife sent for me.

On arriving at their home, I asked, "What does the physician say?" The answer showed that it was a typical case.

---

[12] Walsh, W. T.: Scientific Spiritual Healing, New York, D. Appleton & Co.

The physician had said that the crisis might come any time within the next twenty-four hours, and that while he hoped for the best the balance might turn this way or that and no one could tell which way it would be. Everything depended now on his courage and his fighting spirit.

When I was shown to the patient's room I found him very weak and only partly conscious; at least, so it seemed; but I found out from him later that he was conscious but so weak that he could not give evidence of it. I sat on the bed beside him and gently stroked his forehead. He was restless, so I began to meditate aloud somewhat as follows:

"God says, 'Be still and know that I am God.' Look at me and when I tell you to close your eyes they will close and a feeling of comfort and ease and peace will come about them. To be still means to relax. Now the muscles about your eyes relax and your eyelids close and already there is a feeling of ease and comfort and peace around your eyes.

"That feeling of ease and comfort and peace and well being is going to spread all over the body. Now the muscles of your face and neck relax and your head sinks easily and comfortably on the pillow."

Here I passed my hands over his chest, gently touching him as I continued: "Now the muscles about the chest relax and there is a feeling of ease and comfort and well being all about your chest and around your back.

"There is such ease that you are not conscious of any effort in breathing. [The patient had been breathing with some difficulty when I arrived, but this gradually subsided.] The air is all about you and gently enters your lungs so smoothly and peacefully that it is now a pleasure to breathe.

"God speaks to your mind and says, 'Be still, mind, and know that I am God.' So now your mind relaxes and is still. [illegible]lax means to let go. Your mind lets go of the past. [illegible]bts or fears that might in any wise interfere with the [illegible]g of your body now depart. Your mind is still. It [illegible]o of them and they are gone. Anything that you have heard or thought about your condition that might interfere with your peace or health likewise departs. There is nothing in the past to worry you. On the contrary, out of the past come only words of cheer and confidence, absolute confidence."

Continuing the treatment, I said: "Now your mind lets go of any thought about the future that might in any wise interfere with your well being. There is nothing to fear in the future, for it stretches out before you like a pleasant way and you pass through it confidently, easily and securely. Your mind is now entirely relaxed. It makes no effort. Without any effort you are going to hear and to understand everything I say and no other sound will disturb you.

"God speaks now to the very soul of you, and says, 'Be still and know.' The Scripture says we are partakers of the divine nature. We partake of the life of God. God is the infinite life in all the world. He shares that life with you. God's life is immortal and you are immortal because you partake of the immortal life of God.

"God is the infinite power in all the world. You partake of that power. Deep within you, beneath body and mind, is the life which comes from God. It brings with it the power of God. You partake of his strength. Now the divine power manifests itself in the depths of your nature. It communicates itself to your heart, and your heart beats easily, smoothly, regularly and irresistibly. Your heart feels such power that it knows that nothing can stop it, for the power of God manifests itself there.

"God is infinite vitality. You partake of that divine vitality. God shares it with you. It communicates itself to your heart, and your heart beats with its power. The divine vitality communicates itself to your blood. And now as the blood flows through your body the divine vitality is manifested in every cell and tissue and organ of your body. It takes away all feeling of congestion. It manifests itself in and through your lungs, relieving and strengthening. Every cell and tissue is now cons[illegible] of power an[illegible]ity and health and well being from [illegible] source the infinite source of all courage. Your heart beats courageously. The blood flows along, bringing the message of courage to every cell and organ. Gladly they receive it. Courageously they do their work eliminating and upbuilding. You are surrounded by courage as by the air you breathe, for in the divine courage, in God, we live and move and have our being.

"Even while you sleep you will be breathing in, as it were, life, power, vitality, courage, health and strength and peace. When you awake you will be quite renewed." I then laid my hands on his head and chest, repeating the words of the Scripture, "They that believe shall lay hands on the sick and they shall be healed," and the following prayers: "Almighty Father, according to thy word we lay hands on this, thy servant. May he even at this time be conscious of thy power manifesting itself to the healing of his body, mind, and soul. 'Now unto Him that is able to do exceeding abundantly above that we can ask or think, according to the power that worketh within us, unto him be glory in the church by Christ Jesus throughout all ages, world without end. Amen.'" [Ephesians 3:21.]

The next day I was informed that after I left the sick man he had his first real rest in some days. I continued to treat him daily for about a week, and in due time he was quite restored to health. Toward the end of the time I treated him, he said, "I have a wonderful physician, but I know who saved my life. When you first came to me I felt that I was gradually slipping away. I was too weak and tired to resist. But as you treated me I experienced what you were describing. You brought just what I needed and at the time when I needed it most."

Mr. Walsh places great emphasis on the establishment of expectancy on the part of the patient, and belief that the "healer" can help him. He makes a plea for establishing faith which is based on truth rather than making a practice of taking advantage of imperfect beliefs for temporary gain in the form of curing disease. The ultimate aim of spiritual healing, he says, "includes teaching the patient the whole truth as far as we understand it and he can receive it." He also makes a plea for common sense and the use of medicine so far as this is called for in every case.

Personal treatment with physical healing is a secondary matter. Certain clergymen who have not taken up religious healing as an end in itself report cases from their experience in carrying out the pastoral duties of their office, which would bear witness to the therapeutic value of faith. Professor Batten of General Theological Seminary, who now gives instruction in religious therapeutics at that institution, has had a varied experience along these lines. In the course of his ministry it was not unusual for people who were seriously ill or who had been given up by their physicians to come to him and ask for spiritual help in their distress. Through the calming influence of the religious faith which he was able to build up in them, patients were frequently restored to confidence and enabled to make the most of their remaining days, if not helped to unexpected recovery.

Professor Batten places more confidence in an individual approach, depending on the nature of each particular problem, than on more wholesale methods and regards physical restoration secondary to the establishment of spiritual health with its stabilizing influence. This view is held by many who fear that placing emphasis on physical healing will have a deleterious effect on religion.

Body and Soul Clinic.—This clinic was started by Dr times a week. Certain patients receive additional treatments on nonclinic days at the Park Avenue Hospital, where Dr. Cowles also sees private patients. The work in this clinic is carried on by Dr. Cowles as chief and examining physician, a clergyman and several volunteer assistants, some of whom are previous patients. The doctor talks with each patient and makes such limited physical examinations as the clinic facilities and time permit. Certain laboratory tests are done at a private laboratory to assist in the diagnosis and plan of treatment. When more careful examination is called for by the nature of the case, the director states, patients are referred to other clinics where such examinations may be made.

Treatment at the clinic consists of suggestion administered individually by Dr. Cowles, followed by religious suggestion administered in groups by the clergyman. Immediately preceding the treatment, patients are given a sedative. As he administers suggestion, the doctor presses the closed eyes of the patient, using the fingers of one hand, and with his other hand takes hold of the patient's arm. During this treatment, which consumes only a few moments, the patients lie down in turn on couches provided for the purpose. Nervous and mental diseases seem to predominate. The clinic usually administers to about seventy-five people at a session, mainly young men and women. Patients who have been helped are enthusiastic in their claims of cure and take pleasure in testifying to the efficacy of the treatment, some speaking of it as magic and quite superior to anything they have ever experienced elsewhere. They volunteer this information and recite their testimony in the manner of an oft repeated routine performance. The services of the clinic are free. There is a nominal charge for laboratory examinations when the patient is able to pay for them.

OTHER PROTESTANT CHURCHES

Healing has not been taken up in a systematic way in other Protestant churches, but the interest in it is keen. Many churches have opened their doors to various teachers of the New Thought school. The work takes the form of a series of free public lectures, supported by free will offerings and followed by private courses, which usually cost about $25 for a series of six or eight lectures. Private consultations are also a feature. Other churches have held evangelistic services during the visits of various divine healers to this city. Some physicians report that clergymen have helped them materially in the treatment of particular types of patients. Physicians also enlist the clergyman's aid in the hospitals and in the home when it is felt that his influence will help to raise a patient's morale, as it frequently does with certain types.

Guild of Health.—This organization is of comparatively recent development along lines similar to those of the Nazarene movement, in that it seeks to establish prayer guilds in churches. The Guild of Health, however, confines its work to Protestant churches other than the Episcopal, and emphasizes the educational rather than the ceremonial approach. Rev. Franklyn Cole Sherman, formerly rector of St. Paul's Church in Akron, Ohio, is the founder. The headquarters are in Cleveland. Since its foundation three years ago, it has twice been necessary for the guild to move to larger quarters. Its work is carried on through lectures, literature and personal service on the part of Mr. Sherman. The purposes of the work as stated by Mr. Sherman are:

1. To present a Christian philosophy of life, in harmony with modern philosophy and psychology.
2. To show how the Christian religion can be made practical in the daily life. Special attention is given to problems of mental and physical health.
3. To demonstrate the practical methods that have been found effective, the technic of faith and prayer.

Mr. Sherman is an enthusiast with regard to spiritual healing. He believes that he was himself cured of tuberculosis thereby, and that, if proper technic is developed, all diseases, both functional and organic, may be attacked by this method. Cures, declares Mr. Sherman, are effected by coming into direct conscious communion with God. Although Mr. Sherman feels that in time medical attention will be superfluous, he most firmly expresses the opinion that, until a superior method is developed, physicians and clergymen must and should work hand in hand.

The work of the guild is carried on by donations, membership dues, subscriptions to its official organ, a monthly magazine called *Applied Religion,* and free will offerings.

THE TECHNIC OF MEDICATION

A SERIES OF ARTICLES ON THE METHODS OF PRESCRIBING AND PREPARING, THE INDICATIONS FOR, AND THE USES OF VARIOUS MEDICAMENTS *

BERNARD FANTUS, M.D.
Associate Clinical Professor of Medicine, Rush Medical College
CHICAGO

(Continued from page 1527)

SHAKE MIXTURES

As previously stated, the prescribing of suspensions should, if possible, be avoided. Occasions may, however, arise when it may be desirable to suspend, in watery fluid, either insoluble solids or oils. In the former case, we speak of "shake mixtures" or merely "mixtures"; in the latter case, of "emulsions."

Mixtures, in the pharmacopeial sense, are aqueous liquid preparations that contain finely divided solid matter in partial suspension. Hence, an official mixture is always a cloudy or muddy liquid; as, however, the word is applied in a popular sense to any combination of different ingredients, the term "shake mixture" is more distinctive, and will be used here.

Shake mixtures enable us to administer insoluble substances in fluid form. They have the advantage over powders, divided into separate doses in an appropriate manner, of being less laborious in preparation and therefore somewhat less expensive. Such mixtures have the disadvantage, however, of a certain degree of inaccuracy of dosage; for, even though shaken thoroughly just before taking, a certain amount of separation is liable to take place even while the medicine is being poured. It is for this reason that the prescribing of shake mixtures should generally be avoided. Accurately divided powders, suspended in water just before taking, are preferable. Mixtures containing poisonous sediments should never be prescribed, for they are dangerous. More important is this medicinal form for external use and for the intramuscular administration of certain medicaments, as mercuric salicylate.

---

* This is the twenty-first of a series of articles on "The Technic of Medication." When completed the articles will be assembled in book form.

Should the prescribing of a shake mixture be decided on, it is generally best to add mucilage, syrup or glycerin to the liquid holding heavy insoluble substances in suspension, so as to increase the viscosity of the liquid, thereby lessening the rapidity of separation and increasing the accuracy of dosage.

Perhaps best for the suspending of heavy powders is the (6 per cent) mucilage of tragacanth, from 5 to 10 per cent of which suffices for all purposes. Mucilage of acacia is less efficient, from 25 to 50 per cent of its mucilage being necessary for heavy powders. Syrup or glycerin must be employed in still larger quantities, to be of much service. Nevertheless, there are reasons why glycerin is at times preferable to all others:

1. The other suspending agents do not keep well, having a tendency to ferment, especially in hot weather.
2. Bismuth subnitrate may form with mucilage of acacia a heavy mass that settles to the bottom of the bottle, from which it cannot be dislodged after a few days' standing by even violent shaking.
3. Preparations intended for application to the skin (lotions) containing mucilage are apt to leave an unpleasant sensation of tightness after drying. Glycerin added to the extent of about 5 per cent produces a smoother lotion, without this objectionable tendency. More may be objectionable. Unfortunately, the suspending qualities of glycerin are rather slight.

Because of its liability to ferment on account of the sugar and acacia that was present in it, the chalk mixture of the new pharmacopeia is made with prepared chalk (6 per cent), glycerin (10 per cent), cinnamon water (40 per cent) and water, and is now endowed with good keeping qualities. Its dose is 15 cc., or 1 tablespoonful.

The only other mixture left in the Pharmacopeia is the compound mixture of glycyrrhiza, also known as "brown mixture." This is a typical remnant of the good old days when medicine not only looked brown but also had a rather "dark brown" taste. Its popularity is due to the activity of the 2 mg. of opium and 1 mg. of antimony and potassium tartrate per dose of 4 cc. contained in it, and probably also the fact that the presence of these is not even suggested by the title. As this may lead to the use of an opiate in a cough in which it may not be desirable, it is evident that the ethics of naming a mixture after its most active ingredient cannot be sinned against with impunity even by the Pharmacopeia.

Though not thus named, magnesia magma (milk of magnesia) and ferric hydroxide with magnesium oxide (arsenic antidote) are really mixtures. In each of these cases, advantage is taken of the fact that substances just precipitated—being partly colloidal—are more easily kept in suspension than the same material after it has been dried.

EMULSIONS

Emulsions are mixtures of milky appearance, made by suspending oily or resinous substances in aqueous liquids.

The object of emulsification is to render certain substances that are insoluble in water freely mixable with this fluid, which makes it easier to disguise the taste of substances, facilitates their absorption, and permits admixture of other medicaments.

Two immiscible fluids can, of course, be mixed only if one of these, dispersed into minute droplets (the disperse phase), is suspended in the other fluid (the continuous phase). If oil and water are violently shaken together, they will form a milky fluid—an emulsion—which on standing soon separates into its components. If, however, colloids, such as gum, protein or soap, are present in proper proportion, the separation does not readily occur. Colloids evidently keep the disperse phase from coalescing. Just how they do this is not completely understood. Viscosity and lowering of surface tension are no doubt two influences they introduce that favor emulsification. There may, however, be other factors, such as the formation of a surface film on the droplets of oils and the modification of electric charges. The smaller the droplets, the higher the viscosity; and the more nearly equal the density of the two liquids, the more stable will be the emulsion. Rarely are these factors so perfectly balanced that the emulsion keeps indefinitely. Usually, partial separation takes place sooner or later. However, if the emulsion is well made, mere shaking would suffice to produce uniformity.

Though there is no essential difference between them, emulsions are usually subdivided into two classes: natural emulsions and artificial emulsions. Natural emulsions are exemplified by milk and by yolk of egg. The milk juices existing in plants are natural emulsions, which, when dried, yield an intimate mixture of gum and resin, the gum-resins, which merely require the addition of water to produce an emulsion. The official emulsion of asafetida is an example of this kind of emulsion. It is prepared by rubbing up 4 per cent of asafetida with water and straining. It is used as a carminative. Its dose is given in the U. S. Pharmacopeia at 15 cc. (1 tablespoonful). Probably the best use for this emulsion in tympanites is to give it in much larger dosage by rectum. For peroral administration, as a carminative, asafetida is much more humanely prescribed in capsules.

When oily seeds, as almonds, are rubbed with water, the fat they contain in a fine state of subdivision becomes suspended in the colloidal solution formed by the action of water on the protein of the seed, producing an emulsion. Such a preparation was official in the last Pharmacopeia as emulsion of almond.

The fact that emulsions are rather good emulsifiers may be taken advantage of in the preparation of emulsions in the household. A turpentine enema useful in the treatment of tympanites may, for instance, be prepared in the home by beating from half a teaspoonful to 1 teaspoonful of turpentine with the yolk of an egg, and then gradually adding a pint or a quart of warm water. If these directions are not given and the turpentine is merely mixed with water, the oil floating on the top will enter the rectum last and undiluted, causing a proctitis with its often almost intolerable tenesmus. As another instance of the domestic preparation of an emulsion may be cited the following method of administering castor oil: A cup of milk is heated to the boiling point and shaken up—preferably in a lemonade shaker—with ice cold castor oil. If this is taken immediately, before the oil has had time to separate, no other impression than that of drinking rather rich cream is conveyed to the palate.

If we desire to produce an emulsion of an oil unassociated with an emulsifier, an artificial emulsion, we may do so by simply shaking or triturating the oil with a colloidal liquid, such as mucilage of acacia or extract of malt. A better method, however, consists in reproducing the condition present in gum-resins or in seeds; namely, in first securing an intimate admixture of the oil and the gum, and then adding the water with active trituration, the oil being dashed into globules at the same time that the water dissolves the gum. In order to be successful with this method, it is necessary to have a sufficient quantity of gum mixed with the oil, the most generally useful proportion being 1 part of gum to 4 parts of fixed oil (2 or 3 parts of volatile oil). It is likewise necessary to add enough water to dissolve the gum at once, avoiding, however, an excess of water, which would thin the mucilage, rendering it less efficient as an enveloping agency. A suitable proportion is 2 parts of water for 1 part of gum.

The Pharmacopeia contains a formula for cod liver oil emulsion (dose, 1 tablespoonful), which contains 50 per cent of the oil, 12.5 per cent of acacia, 10 per cent of syrup, and 0.4 per cent of methyl salicylate (wintergreen). The National Formulary affords a variety of other flavors that might be resorted to should the wintergreen flavor pall on the patient's palate. The National Formularly also has a formula for a castor oil emulsion, which contains 30 per cent of oil, and hence may be given in doses of 3 tablespoonfuls.

The official emulsion of oil of turpentine is an example of a volatile oil emulsion. Each average dose of 2 cc. contains 0.3 cc. of oil of turpentine emulsified by 0.1 Gm. of acacia.

In prescribing extemporaneous emulsions, it must be borne in mind that the three essential ingredients in all emulsions are oil or resin, emulsifying agent and water.

Emulsions may be made to contain from 30 to 50 per cent of fixed oil. Volatile oils or similar liquids, as chloroform, creosote or paraldehyde, are not emulsified as readily. Their emulsification is greatly facilitated by first adding to them one-half their volume of a fixed oil, such as expressed oil of almonds, the solution being then emulsified. This is called emulsification by intervention.

The emulsifying agent *par excellence* is acacia. As previously stated, it should be present in the proportion of 1 to 4 of fixed oil, or 1 to 2 of volatile oil. Whenever a physician is in doubt as to the quantity of emulsifying agent needed, he may simply prescribe "a sufficient quantity" of the emulsifier. Resinous tinctures may be emulsified, and thus a perfect mixture be obtained with water, by adding twice the volume of mucilage of acacia, the latter to be diluted with water as much as possible before adding the tincture, in order to prevent precipitation of the gum by the alcohol. Other emulsifying agents are extract of malt, yolk of egg and condensed milk; they have, however, no advantage over acacia. Saponin is an efficient emulsifier; but it has an acrid taste and irritating qualities which render it objectionable for internal use. For external use, on the other hand, especially for emulsifying tar or similar products, it may be used to good advantage in the form of tincture of quillia, 4 parts, to 1 part of tar; water may then be added in any quantity. Soaps, and alkalis by forming soaps, are useful emulsifying agents for external use; they are undesirable for internal use, because of their disagreeable taste, unless the effect of an alkali is also desired, as is the case in the old efficient but nasty "Lafayette mixture," the copaiba mixture of the National Formulary, formerly much employed in urethritis. It contains, in each 8 cc. dose, 1 cc. of copaiba emulsified by the aid of acacia and solution of potassa, 0.24 cc., with peppermint water and syrup in a somewhat abortive attempt at disguising, and 1 cc. of spirit of ethyl nitrite to reinforce its diuretic action.

Emulsions for internal use are generally sweetened with syrup, glycerin, or extract of malt. They are flavored with volatile oils, the quantity of which should not exceed 0.4 per cent, or with tincture of vanilla.

Incompatibilities.—Syrup or glycerin, if added in large amounts, increases the tendency to separation; hence only moderate quantities of these substances, say 25 per cent, are permissible. Acids and acid salts antagonize emulsification, while, as previously mentioned, alkalis and alkaline salts assist. Substances that are incompatible with gum, such as alcohol or ferric chloride, are incompatible with gum emulsions. Tinctures may be added to the extent of 25 per cent or less, provided the alcohol has no marked solvent action on the emulsified substance (as is the case with castor oil).

It must be remembered that emulsions containing acacia, sugar or other fermentable substance, unless they also contain antiseptic ingredients (as alcohol, 10 per cent), do not keep for more than a few days. Hence only moderate amounts, to last for not more than several days, should be prescribed at a time; and the medicine should be kept in the icebox.

The dose of emulsions ranges from a teaspoonful to a tablespoonful. As they are not digested in the stomach, they are best administered about two hours after meals, so as to be introduced into the intestine as promptly as possible. After all that has been said about emulsions it will be realized why it is best, when the dose is large, to let the oil be taken clear, with or without disguise, as previously discussed.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION. W. A. PUCKNER, SECRETARY.

TETRAIODOPHTHALEIN SODIUM (see THE JOURNAL, Sept. 26, 1925, p. 975).

Iodeikon Capsules Swan-Myers.—Each keratin coated capsule contains iodeikon, 0 25 Gm

Prepared by Swan-Myers Co., Indianapolis, Ind.

Communal Health Program.—As, perhaps, the greatest contribution to health is to be accomplished by adequate service for the early diagnosis and preventive or early treatment of disease in hospitals and dispensaries and through the companion agencies of the visiting nurse, social work, the convalescent home, the home for chronics or incurables, the preventorium and sanatorium, we must properly include in our program of communal health those facilities and the costs of them which are needed to provide complete medical care free or at part cost to the sick, whether this be for the acute communicable diseases, tuberculosis, venereal diseases, mental diseases, or for the general medical, surgical, obstetrical and pediatric patients provided for in general hospitals and dispensaries.—Emerson, Haven: *Hospital Social Service* **13:**109 (Feb.) 1926.

UNWARRANTED THERAPEUTIC HOPES

Although drastic restriction in diet no longer characterizes the management of diabetes, the problem of suitable foods for diabetic patients still looms large. Insulin is not a "cure"; consequently the most rational policy at present consists, in the words of Joslin, in utilizing this agent along with all those measures that have proved of the greatest value in the treatment of diabetes without insulin. These are: adherence to a diet that will keep the urine sugar-free; avoidance of overnutrition or extreme undernutrition, and a method of life compatible with the strength that such a diet affords. Side by side with the exclusion of foods that promote either glycosuria or ketosis or both has occurred the search for palatable energy-yielding substances that will enrich the dietary of the diabetic patient without giving rise to the untoward consequences mentioned. The proposal for the use of intarvin (glyceryl margarate) by Kahn of New York, whose untimely death has just occurred, represented an attempt to furnish a fat not likely to promote ketosis in its metabolism.

There have been varied efforts to discover derivatives of the sugars of a chemical character such that they will not escape oxidative destruction as ordinary carbohydrates do in the diabetic organism. Caramel-like substances have been recommended, particularly by German clinicians. There are pitfalls, however, which every one interested in such entirely justifiable attempts must learn to avoid. The polysaccharide carbohydrate inulin, which by hydrolysis readily yields the sugar fructose just as starch yields glucose, has been recommended in the past for patients with diabetes. There are experimental evidences that considerable quantities of inulin, or inulin-bearing vegetables such as the Jerusalem artichoke, may be consumed by such patients without augmentation of glycosuria. This does not guarantee an actual utilization or "assimilation" of the inulin, however. There are no enzymes in the alimentary tract of man that are known to digest inulin, although it can be hydrolyzed by the acid gastric juice. It is conceivable, therefore, that the apparent tolerance of diabetic patients for inulin may be due to actual failure of digestion and absorption of this carbohydrate.

The real index of utilization in such instances is derived from observations of the metabolism—evidences of an actual combustion of the product in question. This is emphasized anew by the recent American studies of commercial glucosane preparations.[1] The anhydrosugar glucosane ($C_6H_{10}O_5$) and its polymer, tetraglucosane, are used in Germany in the dietary treatment of diabetes. These substances are reputed to be oxidized by the diabetic patient since, according to Nothmann and Kühnau [2] and others, no extra urinary sugar results after its administration, no rise in blood sugar occurs thereafter, and an antiketogenic and protein sparing action follows its ingestion. It is likewise reported to be glycogenic. The new American experiments demonstrate that large quantities of ingested tetraglucosane are excreted unchanged in the feces. Part may be destroyed by intestinal bacteria. As Deuel, Mandel and Waddell significantly point out, if a substance like glucosane is oxidized in diabetic patients it can be proved only by the demonstration of an increased respiratory quotient following its ingestion, coupled with the proof of its absorption from the alimentary tract and its nonelimination by the kidneys. Only rigorous experimental work of this sort will protect the enthusiast against the disappointment of ill founded therapeutic hopes.

NEPHRITIS AND NUTRITION

The management of patients exhibiting the varied symptoms commonly classed under the general designation of nephritis has been decidedly modified in recent years. The rationale of treatment has usually been expressed as the effort to rest the kidneys, remove the disturbing cause, and give the renal organs a chance to recuperate. These are obviously laudable purposes; but, when subjected to critical consideration, they lose something of their impressiveness. The implication that the kidneys are the only, or at least the foremost, parts of the body involved cannot be regarded as demonstrated; furthermore, it is by no means as clear today as it seemed to be a generation ago how the "rest" of the kidneys can be secured. At first thought it might seem as though starvation would represent the ideal condition for renal rest, as the function of the kidneys is "to excrete the ashes of food." But, as has often been pointed out, starvation does not rest the kidneys. "A starving person," Emerson [3] has remarked, "lives on himself so long as his body contains anything to live on, and consumes first the stored-up sugar, then the fat, then the protein of the muscles, and the ashes of muscles are more irritating to the kidney than those of milk. One would suppose that a fat and carbohydrate diet would be best, since the ashes of these are eliminated through the lungs. But the body must daily have some fresh protein with which to repair its worn protoplasm." Milk has had the greatest vogue as a food that meets most nearly the requirements of the diseased kidneys; yet the conventional quart of milk a day represents at most a scanty allowance of 750 calories for an organism that requires three or four times as much food fuel. A shortage for a few days can be borne with impunity if not actual benefit; but the treatment of the nephritides is usually a prolonged procedure counted by weeks rather than days, so that a negative balance of energy is sure sooner or later to exhibit the effects of the drafts on the body reserves. No individual organ benefits in the long run by an exhaustion of the organism as a whole.

[3] Emerson, C. P.: Essentials of Medicine, Philadelphia, J. B. Lippincott Company, 1920.

The foremost component of the "ashes" of protein metabolism is urea. There was a time when this catabolite was charged with being the foremost instigator of harm when the renal function is impaired, notably in uremia. As has previously been pointed out in THE JOURNAL[4] and emphasized by recent writers,[5] the general burden of evidence goes to prove that urea concentrations as great as those encountered in the blood of some patients with nephritis are incapable of producing anything resembling the uremic syndrome. An extended investigation of the nonprotein nitrogenous components of the blood in nephritis has also revealed the fact that retention of these waste products may be, and usually is, lacking or an insignificant feature in certain types of nephritis; and notably in those chronic or subacute types which are characterized especially by edema which is not due to cardiac decomposition, the parenchymatous nephritis of older terminologies, the nephroses and the nephrotic forms of glomerulonephritis of Volhard and Fahr.[6] At present there is a recrudescence of the widely held opinion that diets exceptionally rich in protein, particularly in the form of meats, are a provocative of degenerative renal changes.[7] One of the foremost scientific contributions of recent years has been the actual demonstration that in certain types of so-called nephroses the loss of protein through the urine may actually be attended with a serious reduction in the concentration of the plasma proteins. This now constitutes a problem in protein replacement from a new standpoint.

It must be evident to critical students of the subject that the questions reviewed need to be approached with an open mind from new directions. The kidneys should no longer remain the sole center of interest in nephritis, at least so far as treatment is concerned. It is highly important, however, that the pendulum of the new enthusiasm shall not be allowed to swing to other extremes, such as the actual administration of urea or the widespread institution of high-protein diets in nephritis, without a careful scientific control, lack of which has marked the efforts of the past that were motivated by essentially theoretical considerations. Peters and his collaborators[5] at Yale University School of Medicine have pointed out that many nephritic patients present a specious appearance of being well nourished, owing to the existence of some edema. On proper investigation, they give evidence of considerable deprivation of protein, which may be due in part to dietary mismanagement. The further possibility that certain acute stages of parenchymatous nephritis may be characterized by an abnormally high protein metabolism should not be overlooked. The Yale clinicians assert that the total urinary nitrogen of many patients with such disease in acute and chronic forms is not a satisfactory measure of nitrogen breakdown. The latter can be estimated only from the urinary nonprotein nitrogen after proper allowance has been made for changes in blood and tissue nonprotein nitrogen and variations of body weight due to diuresis or accumulation of edema. By the administration of large amounts of carbohydrate and fat it has proved possible to reduce the protein catabolism to from 0.5 to 0.7 Gm. per kilogram daily. If enough protein is given to cover the nitrogen catabolism plus an additional amount equivalent to that lost as albumin in the urine, nitrogen wastage may be prevented. Most of these patients when they enter the hospital show evidences of previous protein deficiency. If they are given more than enough protein to replace the amount lost in the urine, they will store the excess within certain limits, thus repairing the effects of previous inroads on the stores of protein in the body.

High levels of nonprotein nitrogen in the blood are, of course, sources of concern to the clinician. As Peters points out, a positive nitrogen balance cannot be interpreted as evidence of inability on the part of the kidney to excrete protein waste products; nor is a negative balance a sign that the patient is overcoming the effects of such a retention. The nitrogen balance and the level of the blood nonprotein nitrogen are only indirectly dependent on the amount of protein in the diet and are only partly determined by the functional state of the kidney. The rate of nitrogenous metabolism in these cases appears to be the chief determinant of the level of blood nonprotein nitrogen. In the Yale studies the latter has been elevated only in periods when the metabolism was relatively high and usually when there was a negative nitrogen balance. Increasing dietary protein can then be expected to raise the nonprotein nitrogen of the blood only if it raises the protein metabolism of the body.

When such an increase contributes only to the restoration of depleted tissue, it has no such effect. In any event, the day for "depleting" nephritic patients over long periods of time seems to have passed. Adequate nutrition seems to be mostly a blessing, even in nephritis.

GASTRIC ACIDITY

More than a century has elapsed since William Prout presented experimental proof for the contention that the acidity of the gastric juice, by that time a recognized fact, is due to free hydrochloric acid.[1] In his communication to the Royal Society[2] is outlined, step by step, the chemical procedure leading to the evidence on which his significant conclusions were based. The hydrochloric acid was accounted for by the difference between the total chloride and that combined with fixed bases and ammonia. Simple and convincing as Prout's results appear, they were not generally accepted until the extensive studies of Bidder and Schmidt had confirmed them.

Two significant series of investigations had their genesis in these early experiments. One was concerned with the correlation of the quantity of gastric acid secreted with the kind of food undergoing gastric digestion; the other dealt with the origin and mechanism of the elaboration of the acid secretion. The experiments of Pawlow have emphasized the fact that the concentration of gastric hydrochloric acid appears to be greater when proteins are ingested than when other types of foodstuffs are consumed; and the current extensive clinical determinations of gastric acidity have been promoted by these studies. On the other hand, there is at present little convincing proof regarding the place from which, or the form in which, the hydrochloric acid enters the stomach. Enzyme action, vital force and opportune, though naive, reversal of well known chemical reactions have all been invoked in an effort to explain the phenomena. The one definite and apparently well founded conclusion is that the chloride of the gastric juice has its origin in the chloride of the circulation.

In recent studies at the Harvard Medical School, Gamble and McIver[3] have again emphasized the importance of the fixed bases in the gastric juice. These investigators have shown that, in juice obtained from Pawlow pouches in animals, there is a striking constancy in the total chloride concentration. When a diet rich in protein is fed, the total chloride concentration does not vary significantly from the average, but the level of fixed base decreases markedly. As a consequence, an increased acidity usually is observed under such conditions. When, on the other hand, a ration poor in protein is given, the fixed base of the gastric juice is increased. This indicates the probability, as the Harvard investigators point out, that with a nearly constant chloride ion concentration, the fixed base level is adjusted in terms of the amount of ingested material capable of binding chloride ion. Since, as these workers further indicate, the chloride concentration in gastric juice is near the value for the total fixed base in blood, it appears that there is a total ionic equilibrium between plasma and gastric juice. Part of the process of secretion of hydrochloric acid in the stomach may thus be a mass action phenomenon with the food protein playing the part of a base as it would at the existing hydrogen ion concentration.

There are repeated instances of similar "indirect activities" in physiology: oxidation not involving oxygen; hemoglobin carrying carbon dioxide without combining with it; and the activity of antienzymes. Perhaps the long sought explanation for the secretion of acid in the stomach is to be found not in the appearance of acid ions but in a movement of basic ions.

Current Comment

OIL OF WINTERGREEN—A WARNING

Among the substances listed in Useful Drugs[1] is methyl salicylate, more familiarly known as oil of wintergreen, and most commonly used in salves or liniments for external application. When thus absorbed or when taken internally, as is sometimes recommended, the drug produces the effects of salicylic acid or the salicylates. Essentially identical doses are suggested. Quantities of 1 Gm. (15 grains) of oil of wintergreen are repeated every hour or two until "maximal permissible amounts" are given, from 6 to 8 Gm. being required to induce symptoms indicative of the limit of tolerance. Salicylates and closely related compounds have a widespread use as analgesics and antipyretics; and they are among the drugs that the laity not infrequently ventures to employ in self-medication. Where this degree of "familiarity" occurs, dangers of improper use always exist. This is clearly emphasized in a recent report of Wetzel and Nourse[2] indicating, what does not seem to be generally recognized, that methyl salicylate in moderate amounts is a powerful poison. While deaths due to this drug have never resulted from its therapeutic use, instances of untoward effects following accidental or intentional self-administration have been reported. In reviewing the known cases, Wetzel and Nourse ascertained that fatal poisoning may be produced by relatively small amounts of methyl salicylate. Absorption of less than 15 cc. has repeatedly resulted in death. The unexpected toxicity of this drug may be ascribed in part to its comparatively greater lipoidal solubility and in part to the fact that it suffers less destruction within the body after its absorption, when compared with salicylates. In view of the

foregoing circumstances, Wetzel and Nourse believe that the therapeutic use of methyl salicylate should be confined to external administration in the form of a liniment or an ointment; and they point out that Sollmann believes this mode of administration is sometimes more effective than when the drug is given internally. From the standpoint of public welfare, the conclusions of the Cleveland clinicians deserve repetition: Access to oil of wintergreen should be made impossible for children and for persons ignorant of its poisonous properties. A further danger exists in the form of the extract and the spirit of wintergreen, both of which may be in demand because of their alcoholic content.

ARE ENZYMES PROTEIN IN NATURE?

Interest in the physiologic potency of substances that act in great dilution has been accelerated in recent years. The thousands of calories that are requisite for the day's work scarcely arouse more enthusiasm in the student than does the consideration of the almost infinitesimal quantities of certain substances on which our bodily well being seems likewise to be dependent. The alphabetical array of vitamins, the various debated hormones, the enzymes with which digestion and probably other biologic processes are concerned, not to mention other factors such as an occasional fraction of a milligram of iodine, are attracting the attention of the layman as well as that of the scientist. The enzymes represent the longest known "potencies" for producing large effects through small amounts of matter. Naturally there has long been more than a little curiosity as to what these unique substances actually are. From the early history of their investigation it has been realized that they are closely associated with proteins if, indeed, they are not actually albuminous in nature. To assert, as is sometimes done, that enzymes represent the catalytic power of matter in a colloidal state does not promote our understanding of their chemical make-up very much. Enzymes are formed from living matter, and their solutions as usually prepared give the reactions of proteins. However, as Falk[1] has pointed out, the question comes up here again as to whether the compositions as shown by such analyses do not represent merely the source of the enzyme material. The enzyme property might well be only a small part of even the purest preparation that has been separated, and the analyses which have been given only show the general composition of the medium, if this term may be used, which carries or accompanies the enzyme. Nitrogenous substances, mainly of protein nature, form a part at least of all enzyme preparations. In the course of his efforts to "purify" enzymes, Willstätter has lately questioned the conclusion that certain enzymes, at least, are protein in nature. A reinvestigation of the subject by Sherman[2] and his co-workers at Columbia University, in the case of pancreatic amylase as a type, confirms his earlier conclusion that the enzyme either is of protein nature or contains protein as an essential component. This is not the place to review the details of the evidence. It helps us to understand why antiseptics that act chemically on proteins are enormously more destructive of the enzyme than are the antiseptics of the lipoid-dissolving type.[3] Sherman confronts us with the startling announcement that his purified pancreatic amylase has digested as much as 4,000,000 times its weight of starch and formed as much as 2,800,000 times its weight of maltose. This great enzymic activity was shown at a dilution of 1 : 100,000,000, whereas the most delicate tests for protein are probably not valid at dilutions greater than about 1 : 100,000. Thus the failure of protein reactions in solutions enzymically active does not show, as many writers assume, that the enzyme is of other than protein nature, since, as in this case, the enzymic activity may constitute a test a thousandfold more delicate than any reaction that can be employed as a test for the presence of protein material.

UREA AND THE LIVER

Not long ago a group of investigators[4] at the Mayo Foundation furnished evidence that the production of urea is entirely dependent on the functioning of the liver in the body; at any rate, urea formation evidently ceased when this large glandular organ was extirpated. The technic of the research was brilliant and the demonstration so cogent that this contribution is likely long to remain one of the classic studies in experimental physiology. The conclusions to which they led seem to be established beyond unfavorable criticism. Nevertheless, it is gratifying to note, in recent observations by Morgulis,[5] a confirmation of the significant thesis as to the specific rôle of the hepatic cells in relation to urea. The argument has been advanced that, to prove the liver to be the predominant place for urea formation, it is necesssary to show that during the early stages of the absorption of amino-acids the increase in the urea content of the blood precedes the increase in its content of amino-acids. As Morgulis formulated the question, it is clear that a preliminary rise in amino-acid nitrogen would not necessarily preclude the possibility of the liver's being the specialized organ for deamination and urea formation, whereas the rise in urea nitrogen preceding a rise in amino nitrogen would furnish positive proof of the liver's important rôle as an organ of urea formation. The tests of Morgulis at the University of Nebraska College of Medicine demonstrate that after feeding protein *products the urea nitrogen of the blood "rises either* before there is an appreciable increase in the blood amino-acids, or, when the rise is concomitant, the urea nitrogen increase is much more striking." In this connection Morgulis ventures the suggestion that what we generally designate as "urea formation" may in reality not represent a single process at all. It is not improbable that the deamination of the amino-acids and the synthesis of urea may be independent processes. It may not be amiss to repeat an earlier statement in

The Journal:[6] In two years, chemists throughout the world will celebrate the centenary of Wöhler's classic synthesis of urea—the first compound of biologic origin to be duplicated synthetically in the laboratory without the intervention of "vital" processes. May we not hope that the celebration will be enriched by a more complete understanding of how urea is synthesized by nature—in the liver?

Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

CALIFORNIA

Personal.—Dr. Lester B. Rogers, formerly medical director of the U. S. Veterans' Bureau, has accepted the position of medical director of the St. Francis Hospital, San Francisco.

Physician Sentenced.—Dr. Earl Harlan, Colusa, was found guilty of violation of the Harrison Narcotic Law, it is reported, and was sentenced to three years in a federal prison, March 13.

Health at San Diego.—Telegraphic reports to the chamber of commerce from sixty-nine cities with a total population of about 29,000,000 for the week ending May 1 indicate that the highest mortality rate (22.1) was for San Diego, and, that the rate for the group of cities was 14.4. The mortality rate for San Diego for the corresponding week last year was 18.7, and for the group of cities, 13.7.

University News.—Stanford University Medical School recently received $1,000 from Dr. Morris Herzstein for the establishment of a lectureship on the diseases of the Pacific Basin.——Dr. Frederick L. Reichert of Johns Hopkins University Medical School, Baltimore, has been appointed associate professor of surgery in the Stanford University Medical School, beginning with the year 1926-1927.

DISTRICT OF COLUMBIA

Personal.—Dr. Hubert Work, secretary of the interior, and former president of the American Medical Association, was reelected president of the Medical Veterans of the World War at the annual dinner at Dallas, Texas, in April.

Hearings on Antivivisection Bill.—Hearings were held, May 6, before a senate committee on the bill introduced by Senator Fletcher of Florida, which would prohibit vivisection among dogs in the District of Columbia, the territories and our insular possessions. Among those who appeared in opposition to the bill were Dr. Reid Hunt, professor of pharmacology, Harvard University Medical School, Boston; Major Henry J. Nichols, Army Medical Corps; Lieut. Comdr. Joseph R. Phelps, Navy Medical Corps; John S. Buckley, chief, pathologic division, Bureau of Animal Research; Alice C. Evans, Mrs. Ella A. Enlows, Hygienic Laboratory, and Dr. Victor C. Vaughan, chairman of the medical section of the National Research Council.

Bureau of School Hygiene Proposed.—The establishment of a bureau of school hygiene in the health department of the District of Columbia is proposed in a bill introduced, May 3, by Congressman Begg of Ohio. The bureau would provide medical examinations for all pupils in public and private schools of the district; medical examinations for teachers in public schools; sanitary inspections of schools and school equipment, and nutrition classes. The bill is the outgrowth of an investigation begun by the Monday Evening Club, which showed that Washington is far behind other cities in safeguarding the health of school children. In commenting on the bill, Congressman Begg said: "Today the development of health is recognized by all educational leaders as one of the primary objects of all education. Cities throughout the country recognize the great importance of this work, but in this movement the capital of our nation is far behind. The situation calls for serious attention."

FLORIDA

Health at Jacksonville.—Telegraphic reports to the department of commerce from sixty-seven cities with a total population of about twenty-nine million for the week ending April 17 indicates that the highest mortality rate was for Jacksonville (22.4), and that the mortality rate for the group of cities was 15.8. The rate for the corresponding week last year in Jacksonville was 14.9 and for the group of cities as a whole, 14.5.

ILLINOIS

Resolution About Anesthetics.—The Rock Island County Medical Society, Moline, passed a resolution, May 11, reiterating, among other things, that the giving of anesthetics is the practice of medicine, and resolving that it shall be unethical for any member of that county society to employ any one but licensed and qualified physicians to administer anesthetics except under supervision in emergency.

Society News.—Dr. Augustus G. Pohlman, professor and director of the department of anatomy, St. Louis University School of Medicine, St. Louis, gave an illustrated lecture before the Peoria Medical Society, Peoria, May 4, on "An Interpretation of Rudimentary Organs in the Human Body."——Dr. George E. Shambaugh, Chicago, was guest of honor at a dinner given by the Morgan County Medical Society, May 3.——The Medical and Dental Arts Club, Chicago, will give a dinner at the Sherman Hotel, May 27, 6:30 p. m.; members may bring with them as guests of the club other physicians and dentists.

LOUISIANA

The "Grace Grey" Commissioned.—The new boat of the Louisiana State Board of Health, *Grace Grey*, will make its first inspection trip of the Louisiana oyster beds next week; the boat is 48 feet long.

"Dr. Remington" Sentenced.—Charged with representing himself as an agent of the U. S. Public Health Service and of the department of justice, William E. Krebs of Ohio, alias Dr. R. M. Remington, alias Andrew B. Walker, was found guilty by a jury in New Orleans, April 13, and sentenced to two years in the federal penitentiary at Atlanta, Ga., it is reported; on the strength of his misrepresentation, Krebs is said to have been able to cash a draft on a bank which did not exist.

Society News.—The Orleans Parish Medical Society voted to raise its dues, beginning March 1, to a dollar and a half a month. The board of directors of the society has voted to set aside $250 annually from the increase in dues, to be used to invite some prominent speaker to deliver an oration, to be known as the "Stanford E. Chaille Oration."——Dr. Alfred P. Crain has been elected president of the Shreveport Medical Society, which society has appointed a committee to make arrangements for a modern medical library to be housed in the Shreveport Memorial Library.

Roentgen-Ray Department Dedicated.—A banquet was held at the Touro Infirmary, New Orleans, April 27, to celebrate the completion of the new roentgenologic department, which was made possible through a donation by the daughters of the late Emanuel Sternberger, in memory of whom the donation was made. Drs. Rudolph Matas, New Orleans, James T. Case, Battle Creek, Mich., Emanuel Libman, Columbia University College of Physicians and Surgeons, New York, and Mayor O'Keefe, New Orleans, were among the speakers. The new department has separate rooms for general radiography, fluoroscopy, cystoscopy and deep roentgen-ray therapy.

Personal.—Dr. David A. Lines has resigned as collector of internal revenues at New Orleans, effective, May 1.——Dr. Stanford Chaille Jamison has been elected president of the New Orleans Tuberculosis and Public Health Association; Drs. David L. Watson and J. George Dempsey were elected vice presidents of the association.——Dr. William Johnson, New Orleans, was elected president of the Louisiana Child Finding and Home Society, April 27.——Dr. Lucian H. Landry, New Orleans, has been reelected president of the Tulane Alumni Association.——Dr. William Scheppegrell has been reelected president of the New Orleans Zoological Society.

Record Rainfall Damages Hospital Supplies.—A rainfall in New Orleans of 9.08 inches in the twenty-four hours following May 2 exceeded all previous records of the Weather Bureau for May, and caused damage estimated by the *Times Picayune* at more than $100,000. Water burst open the basement doors of the Southern Baptist Hospital, damaging supplies to the extent of about $60,000 and flooding the basement to the depth of more than 4 feet. Visitors and others were marooned in the hospital for the night, the hospital grounds also being submerged to a depth of about 2 feet. This deluge was surpassed in New Orleans in 1883, however, when the rainfall for a twenty-four period amounted to 9.22 inches.

---

[6] The Liver and Urea Formation, editorial, J. A. M. A. **83**: 1336 (Oct. 25) 1924.

MARYLAND

Deaths from Rabies.—Of the seven deaths from rabies in Maryland from 1911 to 1925, four, says the state department of health, occurred in 1925. There were 183 persons who were given Pasteur treatment in 1925, or more than double the number treated in any previous year. Not any of the four persons who died in 1925 had received the Pasteur treatment, and not one of those who took the treatment developed the disease.

Tuberculosis Institute.—Dr. William H. Welch, director, Johns Hopkins School of Hygiene and Public Health, gave the opening address at the regional institute for tuberculosis workers, April 12. Meetings were held twice daily for about two weeks and attended by persons engaged in tuberculosis work in Maryland, Pennsylvania, New Jersey, New York, West Virginia, South Carolina, Colorado and the District of Columbia. Among the other speakers were Philip P. Jacobs, Ph.D., publicity director of the National Tuberculosis Association; Dr. Martin F. Sloan, president, Maryland Tuberculosis Association, and Dr. William J. McConnell, connected with the Philadelphia Health Council.

Annual Conference of Health Officers.—At the annual conference of health officers and boards of health of Maryland to be held at Johns Hopkins School of Hygiene and Public Health, Baltimore, May 28-29, under the auspices of the state board of health, Governor Ritchie will make the opening address; among others, Dr. R. Eugene Dyer, assistant director, Hygienic Laboratory, Washington, D. C., will discuss "Scarlet Fever Immunization"; Dr. George H. Ramsey, deputy commissioner, Michigan State Department of Health, Lansing, "Diphtheria Immunization as an Administrative Public Health Problem"; Dr. Robert H. Riley, chief, Maryland Bureau of Communicable Diseases, "The Typhoid Situation in Maryland." Physicians, health officers and any other interested officials have been invited to attend the conference.

MASSACHUSETTS

Dr. Lund Resigns.—Dr. Fred B. Lund has resigned as surgeon in chief of the Boston City Hospital, according to the Boston *Herald,* to become chief of the surgical staff of the Carney Hospital. Dr. Lund has been connected with the Boston City Hospital for nearly thirty years.

State Sanatorium Opened.—More than 300 physicians, students and others attended the formal opening of the Lakeville State Sanatorium, April 27, and made a tour of the buildings and the model dairy connected with the sanatorium. Among the speakers were the governor, Alvan T. Fuller; Dr. James S. Stone, president of the Massachusetts Medical Society, and Dr. Linsly R. Williams, director of the Massachusetts Tuberculosis Association.

Society News.—Dr. George L. West, Newton Center, has been elected president of the Middlesex South District Medical Society, and Stephen M. Biddle, Cambridge, secretary. ——At the annual meeting of the Berkshire District Medical Society, Pittsfield, April 29, Dr. Richard Lewisohn, New York, spoke on "Transfusion by the Citrate Method: Technic, Indications and Results."——Dr. Linsly R. Williams, managing director, National Tuberculosis Association, among others, addressed the annual meeting of the Massachusetts Tuberculosis League, April 26, Boston; at the meeting Dr. Kendall Emerson, Worcester, was elected president of the league, and Dr. Frederick T. Lord, Boston, vice president.——Dr. Leo M. Davidoff, Boston, gave an illustrated lecture at the annual meeting of the Essex South District Medical Society, Gloucester, May 11, on "A Trip to the Far North with MacMillan."

MINNESOTA

Hospital News.—The Oakland Park Sanatorium is to erect a $30,000 addition; this institution is the State Tuberculosis Hospital of Pennington, Marshall, Roseau and Red Lake counties.——The Ancker Hospital, St. Paul, is constructing a new five story contagious department which will have a capacity of 280 beds.

Society News.—Dr. Willis C. Campbell, professor of orthopedic surgery, University of Tennessee College of Medicine, Memphis, addressed the Minnesota Orthopedic Club, April 6, at the University of Minnesota, Minneapolis, on "Immobilization of Joints."—Dr. E. T. F. Richards addressed the Academy of Medicine, April 14, at the Town and Country Club, Minneapolis, on "Infectious Mononucleosis"; Dr. John G. Cross addressed the Minnesota Academy of Medicine at the Town and Country Club, Minneapolis, May 12, on "The His Bundle and Its Disturbances."

NEW HAMPSHIRE

State Medical Meeting.—The one hundred and thirty-fifth annual meeting of the New Hampshire Medical Society will be held at the state armory, Concord, May 25-26, under the presidency of Dr. Thomas W. Luce, Portsmouth. Among the guests will be Dr. Charles H. Mayo, Rochester, Minn., who will speak Wednesday on "Developmental Anomalies, Especially of the Genito-Urinary Tract"; Dr. William H. Park, New York, "Use of Scarlet Fever Toxin and Antitoxin in the Prevention and Cure of Scarlet Fever"; Dr. James P. O'Hare, Boston, "Chronic Nephritis and Hypertension," and Dr. Walter W. Chipman, Montreal, on "Etiology and Treatment of Dysmenorrhea." Governor and Mrs. Winant will entertain members, ladies and guests at their home, Tuesday evening; there will be automobile excursions for the ladies, Wednesday, and the annual banquet Wednesday evening at the Eagle Hotel. The state association of local health officers and the state association of registered nurses will meet in Concord at the same time as the medical association.

NEW JERSEY

Home for Babies.—The Ocean City Seashore Home for Babies will open its wards for the season, June 1, and will close, September 15. Information as to the type of patients admitted may be obtained from the medical director, Dr. Henry H. Perlman, 1904 North Franklin Street, Philadelphia.

Society News.—Dr. Edward A. Strecker, professor of neurology, Jefferson Medical College, Philadelphia, addressed the Camden City Medical Society, May 11, on "The Psychology of the Normal Child."——Dr. Stanley M. McGeehan, Atlantic City, reported a case of granuloma inguinale before the Atlantic County Medical Society, May 14. ——Dr. Louis C. Williams addressed the Hunterdon County Medical Society at Flemington, April 27, on "Treatment of Erysipelas by Heliotherapy."

State Medical Meeting.—The annual meeting of the Medical Society of New Jersey will be held at Haddon Hall, Atlantic City, June 17-19. Among other things, there will be a symposium on cardiovascular renal disease opened by Dr. Frederick M. Allen, and a symposium on urology opened by Dr. Hugh H. Young, of the Brady Clinic, Johns Hopkins University, Baltimore; Dr. Samuel W. Lambert, New York, will direct a moving picture, "Exhibition of Heart Lesions." A program of unique entertainment has also been arranged.

Chiropractors in Court.—The Board of Medical Examiners of New Jersey submits the following list of chiropractors who have been brought recently into court, charged with practicing medicine without a license. All but four, who were put in jail, paid fines:

Charles H. Witter, Dunellen.
Raymond O. Danese, Hudson Heights (put in jail for twenty days).
Floyd Farrell, Hackensack.
Regina B. Heim, Newark.
Cyril H. Guterl, Jersey City.
Roy Pierce, New York.
Alson J. Walker, Orange (put in jail for fifteen days).
Mary Bumby (tried in Elizabeth District Court and jailed for one day).
Clarence U. Pole, Audubon.
William Joseph, Collingswood.
Jack M. Blank, Camden.
Thomas S. Dukes, Camden.
Andrew J. Corey, Verona.
Joseph Bowley, Burlington.
Charles R. Breamer, Pleasantville (put in jail for ten days).
Hugh M. Condie, Camden.
Kathryn Mikle, Fairview.

NEW YORK

Medical School Announces Opening.—The University of Rochester announces that the formal opening of its School of Medicine and Dentistry will be, October 25-26. There will be scientific medical conferences on these days; papers will be presented by Prof. Friedrich Müller, Munich; Dr. Charles J. Martin, president of the Lister Institute of London, and other leaders in medical science. Formal invitations will be issued in September.

Governor Signs New Medical Practice Act.—Governor Smith has signed the new medical practice act, recently passed by the state legislature and known as the Webb-Loomis bill. This legislation, drafted, primarily, to protect the public against unqualified and illegal practitioners, was described and commented on in The Journal, May 1, p. 1354. ——The governor announced, May 17, that he had vetoed a bill which would have permitted chiropodists and podiatrists to use the title "doctor" or its abbreviation.

New York City

Resolution on Commercialized Lectures.—The executive committee of the New York Electrotherapeutic Society has unanimously passed the following resolution:

> Whereas, Various commercial concerns and enterprises dealing in electrotherapeutic and allied apparatus are with increasing frequency holding public lectures in New York, which are in effect and in fact nothing more than lectures advertising their goods; and
>
> Whereas, Audiences to those lectures are not limited to members of the medical profession; and
>
> Whereas, The lectures themselves are not carefully selected or given, and
>
> Whereas, The audience must necessarily be misled; be it therefore
>
> *Resolved* By the Executive Committee of the New York Electrotherapeutic Society that the department of health should control such lectures by licenses after due and proper investigation, so that the public may be protected from the aforesaid abuses.

New Vanderbilt Clinic.—President Nicholas Murray Butler of Columbia University announced, May 4, that Frederick W. and Harold S. Vanderbilt have given $500,000 to rebuild the Vanderbilt Clinic in connection with the new medical center which is now in the course of construction. The Vanderbilt Clinic was established in 1886 by the brothers Cornelius, William K., Frederick W. and George W. Vanderbilt. It always has been an integral part of Columbia's work in medicine, and the new institution, President Butler said, will correlate and unite the entire teaching now carried on by the university at the clinic on Amsterdam Avenue and Sixtieth Street, at the outpatient department of the Presbyterian Hospital at Madison Avenue and Seventieth Street, and at Bellevue Hospital. President Butler also announced the receipt of another anonymous gift of $125,000, to be expended at the discretion of the board of trustees for the benefit of the medical school.

Personal.—Michael M. Davis, Jr., Ph.D., executive secretary of the committee on dispensary development, United Hospital Fund, has gone to Europe to study outpatient clinical methods.——Dr. James F. Cooper of the American Birth Control League recently made a speaking tour through New England addressing numerous medical societies and other organizations on the subject of birth control; April 4, Dr. Cooper addressed the Orange County Medical Society at Orlando, Fla; March 30, a meeting of physicians at Roanoke, Va.; March 31, a special meeting in Johnson City, Tenn.; March 29, the county medical society at Cumberland, Md.; April 1, the Medical Society of Chattanooga, Tenn., and April 2, the Roane County Medical Society, Harrison, Tenn.——Dr. Joseph J. Eller has been elected president of the Manhattan Dermatological Society for the ensuing year. ——Dr. Manuel Uribe Troncoso has been promoted to professor of ophthalmology in the New York Post-Graduate Medical School and Hospital.——Dr. Charles C. Williamson, formerly director of information service of the Rockefeller Foundation, has been appointed director of the libraries of Columbia University.——Dr. Alexander Lambert has been elected a director of the New York Tuberculosis and Health Association.——Queens University, Kingston, Ontario, Canada, conferred the honorary degree of LL.D. on Dr. William H. Rankin, May 6, who graduated from that institution thirty-seven years ago.

OREGON

Society News.—Dr. Frank W. Lynch, professor of obstetrics and gynecology, University of California Medical School, gave the annual lecture on gynecology before the Portland Academy of Medicine, April 8, and was guest of honor at a dinner given by the president, Dr. Stuart H. Sheldon, at the Arlington Club.

Personal.—Dr. George E. Fortmiller, Albany, has been elected president of the Albany General Hospital Association, succeeding the late Dr. James P. Wallace.——Dr. Harry Y. Spence, Eugene, has been appointed Red Cross instructor in first aid for the Pacific Division.——Dr. Ernst A. Sommer, Portland, has been reelected president of the Oregon Public Health League, and Dr. Frederick D. Stricker, Portland, secretary, reelected.

Illegal Practitioner Fined.—"Dr." George Kirkpatrick, it is reported, was fined $100 in the district court at Portland, April 12, after a jury had found him guilty of practicing medicine without a license. A complaint was filed against Kirkpatrick by the Oregon Public Health League, it is said, when he was found to be selling some "cure" for ten dollars a bottle. Kirkpatrick's "Pul-Bro-Tu", a consumption cure, so called, was the subject of an article under the propaganda department of The Journal, March 6.

Hospital News.—Drs. Herbert C. Eastland and Charles Billington are in charge of the new emergency hospital opened in Reedsport.——The Pacific Christian Hospital at Eugene has just added twenty-four beds by remodeling the fifth floor. ——The La Grande Hospital has installed a new roentgenray outfit.——The Dallas Hospital, Dallas, announces that it will construct a thirty room addition, and that Dr. William R. Taylor, Forest Grove, will be added to the staff.——The Klamath Indians have protested against the establishment of a tuberculosis sanatorium at their agency.

PENNSYLVANIA

Hospital for Crippled Children.—Construction work on the first units of the state hospital for crippled children will start in the near future. The site for the hospital is in Lancaster County just west of Elizabethtown on the Harrisburg and Lancaster Pike; it comprises about 245 acres, of which about 60 are woodland; also a modern dairy barn, which will be retained by the state. The water supply will be from the Elizabethtown Water Company; the institution will be connected with the new sewage disposal plant erected in Elizabethtown, and electricity is already on the grounds.

State Welfare Department.—A pamphlet describing the work of the state welfare department was recently issued by the public Charities Association of Pennsylvania, 311 South Juniper Street, Philadelphia. The state welfare department was created by an act of the state assembly in 1921, which united and coordinated a number of different bureaus and added the duties of supervising all agencies for the care of children. The new department took over the duties of the old Board of Charities, the Committee on Lunacy, the Mothers' Assistance Fund and the Prison Labor Commission. The state welfare department now has four bureaus: (1) Bureau of Children, (2) Bureau of Assistance, (3) Bureau of Mental Health and (4) Bureau of Restoration. This pamphlet may be obtained, free of charge, from the public Charities Association.

Philadelphia

"Travel Trip" of Southern Internists.—The Southern Interurban Clinical Club of Internists made its fifth "travel trip," May 6-7, when it was the guest of the University of Pennsylvania Hospital, the Philadelphia General Hospital and the Jefferson Hospital; clinics, demonstrations and papers were presented. Dr. Isaac I. Lemann, New Orleans, is president of the club, and Dr. Bryce W. Fontaine, Memphis, Tenn., secretary-treasurer.

Personal.—At the recent dedication of the Philadelphia County Medical Society's new building, Dr. James M. Anders spoke on the efforts of the society, covering a period of fifteen years, to secure a suitable home.——Dr. William H. Perkins sailed from New York, May 4, for Europe to study medical teaching methods before taking up again his post in Siam under the Presbyterian Board of Foreign Missions; Dr. Perkins left Siam in 1923 to do postgraduate work at Jefferson Medical College; later he was on the staff of the Philadelphia General Hospital.

Society News.—Drs. Nathaniel W. Winkelman and George Wilson addressed the Philadelphia Psychiatric Society, May 14, on "A Clinicopathologic Study with Especial Reference to the Significance of the So-Called Typical Laboratory Findings in General Paresis", and G. E. Partridge, Ph.D., and Dr. Clifford B. Farr on "Current Conceptions of Bodily Structure in Relation to Temperament and Character."—— About 350 members of the Philadelphia Medical Club visited the Naval Academy, Annapolis, Md., May 13, where, following a luncheon at Carvel Hall, they were escorted on an inspection tour by naval officers.

Seminars on Physical Therapy.—The Philadelphia County Medical Society is conducting a series of five seminars on physical therapy at its new home, Twenty-First and Spruce streets, the purpose of which is to discuss informally the various aspects of the subject. Dr. Ralph Pemberton was in charge of the May 14 seminar, "Thermotherapy and Hydrotherapy"; Dr. Theodore H. Weisenburg, May 21, "Massage and Manipulation with Demonstrations"; Dr. Frederick A. Cochran, Jr., will be in charge, May 28, "Light Therapy";

Dr. William T. Johnson, June 11, "Diathermy"; the subject for June 4 will be "Radiology"; the speakers will be announced later.

TENNESSEE

Fiftieth Anniversary.—The Memphis and Shelby County Medical Society celebrated its fiftieth anniversary, May 13, at the University Club, Memphis, where a buffet supper was served. Dr. Elmer E. Francis spoke on "The History of Medical Education in Memphis"; Dr. John M. Maury, on "The History of Hospitals in Memphis"; Dr. Richmond McKinney, "History of Medical Journalism in Memphis." Other speakers were Drs. Benjamin F. Turner and William Krauss.

Personal.—Dr. Edward D. Mitchell was elected president of the Women's Hospital of Memphis at the recent annual meeting.——Dr. Martin H. Fischer, head of the department of physiology, University of Cincinnati College of Medicine, will deliver the address at the graduating exercises of the University of Tennessee Colleges of Medicine and Dentistry and School of Pharmacy, June 7, in the city auditorium at 8 o'clock.——Dr. John R. Caulk, St. Louis, who was entertained at dinner, April 6, by members of the Memphis Urologic Society, addressed the Memphis and Shelby County Medical Society that evening.

VIRGINIA

Personal.—Dr. Vincent W. Archer has been promoted from instructor to assistant professor of roentgenology on the faculty of the University of Virginia Department of Medicine, and Drs. Henry B. Mulholland and James E. Wood, Jr., from instructors to assistant professors in internal medicine; the promotions are effective at the next session.

New Medical Organizations.—The Princess Anne County Medical Society has been reorganized; meetings will be held monthly at the Seaside Cottage Sanatorium, Virginia Beach. ——Charlotte County physicians have applied for a charter for the Charlotte County Medical Society, of which Dr. Charles W. Tucker, Drakes Branch, was elected president at the meeting, April 16; the Cumberland County Medical Society has also applied for a charter; at the organization meeting, Dr. Carter Weisiger, Cumberland, was elected president.——The women physicians of Richmond recently issued invitations to all women physicians in the state who are members of the Medical Society of Virginia to attend an organization meeting, April 5, at which the Virginia Medical Women's Club was organized; Dr. Mary B. Baughman, Richmond, was elected president, and Dr. Cora Z. Corpening, Virginia Beach, secretary-treasurer.——Physicians of ten counties met, April 17, at Farmville, and organized the Central District Medical Society of Virginia. Among the guests at the meeting were Dr. William L. Harris, Norfolk, and Miss A. V. Edwards, Richmond, president and secretary, respectively, of the Virginia State Medical Society. Dr. Paulus A. Irving, Farmville, was elected president of the new society; Dr. Ray A. Moore, Phenix, vice president, and Dr. William E. Smith, Farmville, secretary-treasurer.

WASHINGTON

Personal.—Dr. Minard Allison, Monroe, has been appointed physician to the state reformatory at Monroe, to succeed the late Dr. Harry K. Lum.——Dr. William R. Leverton has resigned from the U. S. Veterans' Hospital at Tacoma to take charge of the physiotherapy department of the Tacoma General Hospital.——Dr. Frank Dwyer, formerly of Sedro-Woolley, has been appointed assistant superintendent of the Western State Hospital at Fort Steilacoom.——Dr. Charles S. Hood, Ferndale, has been elected president of the Whatcom County Physicians and Surgeons Club.

Society News.—Dr. E. Frank Chase, Seattle, has been elected president of the Puget Sound Academy of Ophthalmology and Otolaryngology; Drs. John A. Johnson, Tacoma, and Spencer S. Howe, Bellingham, vice presidents, and Dr. Morrill J. Morris, Seattle, secretary-treasurer.——A ten-story medical arts building, costing $250,000, will be constructed at Yakima.——The Medical Section of the King County Medical Society, Seattle, will devote the May 17 and June 21 meetings to a symposium on pulmonary tuberculosis, the former being on the anatomic pathology and the latter on treatment.——Dr. Sidney S. Oppenheimer, president of the Washington State Medical Association, and Dr. George A. Downs, of the public health league, addressed the Walla Walla County Medical Society, April 9.

WEST VIRGINIA

State Medical Meeting.—At the fifty-ninth annual meeting of the West Virginia State Medical Association, Morgantown, May 25-27, under the presidency of Dr. James R. Bloss, Huntington, Dr. Orrin S. Wightman, New York, will discuss "Periodic Health Examination of the Apparently Healthy," and Dr. Southgate Leigh, Norfolk, Va., "Problems Confronting the Profession"; Dr. John H. J. Upham, Columbus, Ohio, a trustee of the American Medical Association, will deliver the oration on medicine, Tuesday evening, and Dr. Chester R. Ogden, Clarksburg, the oration on surgery; Dr. Walter G. Stern, Cleveland, Ohio, will speak, Wednesday morning, on "Some Problems of Modern Orthopedic Surgery." Among other visiting speakers will be Dr. Edward A. Looper, Baltimore; Dr. John B. McMurray, Washington, Pa.; Dr. Paul Titus, Pittsburgh; Dr. Leo Brady, Baltimore; Dr. Verne C. Hunt, Rochester, Minn.; Drs. Joseph E. Moore and Albert E. Goldstein, both of Baltimore, and Dr. Magnus A. Tate, Cincinnati. There will be demonstrations daily at the West Virginia School of Medicine from 2 to 3 p. m. The annual banquet will be Thursday evening.

GENERAL

Automobile Fatalities.—Reports to the department of commerce from seventy-nine large cities for the four weeks ending April 24 show that 424 persons were killed by automobiles, as contrasted with 350 for the preceding four weeks. Eleven cities had no automobile fatalities in the four weeks preceding April 24; Erie, Lowell, New Bedford, Utica and Waterbury had no fatalities during the last eight weeks, and New Bedford and Waterbury had none during the last sixteen weeks.

Accidents in Coal Mines in March.—There were 169 deaths among employees due to accidents in coal mines in March, according to the bureau of mines; 132 of these deaths were in the bituminous mines and thirty-seven in the anthracite mines. There was an explosion, March 8, at Eccles, W. Va., which killed nineteen men and made the total number of major disasters in 1926, to date, seven; for the same period in 1925, there were only three major disasters in mines. The records of the bureau of mines for the first three months of 1926 show 658 fatalities, while for the corresponding period last year they show 630.

The Incubus of the Harrison Narcotic Act.—THE JOURNAL, May 8, commented on a bill which has been introduced in the U. S. Senate "to strengthen" the Harrison Narcotic Act. It was pointed out that this bill would impose additional duties on physicians with respect to the use of narcotics, increase the penalty for violations of the act, and limit the right of physicians to use narcotics. In another section of the same issue of THE JOURNAL the bill was discussed at length. Now a bill of the same purport (H. R. 11612) has been introduced in the House of Representatives. As was stated in THE JOURNAL, the hearings on these bills will be awaited with interest.

Lost—List of Two Hundred and Fifty Names.—At the annual dinner of the Medical Veterans of the World War during the convention at Dallas, Texas, more than 250 physicians gave their names to the secretary, Dr. Arthur T. McCormack, to be enrolled as members. On the way home on the train, these names and other things were stolen from Dr. McCormack's grip, and it is impossible to enroll these members until the list is recovered. Dr. McCormack requests that all those who gave him their names at Dallas, and others who desire, forward their names to him at Louisville, Ky. This organization will soon begin publishing a quarterly which will be devoted almost entirely to the personal history of physicians who served in war.

Society News.—The National Association for the Study of Epilepsy will hold its twenty-fifth anual meeting at the Waldorf-Astoria Hotel, New York, June 7-8, immediately preceding the meeting of the American Psychiatric Association.——At the annual meeting of the American Society of Clinical Investigation, May 3, Atlantic City, N. J., Dr. Eugene F. Du Bois, Cornell University Medical School, New York, was elected president, and Dr. Joseph T. Wearn, Boston City Hospital, Boston, secretary; the next annual meeting will be at Atlantic City, May 2, 1927.——At the annual meeting of the American Gastro-Enterological Association, Atlantic City, N. J., May 3-4, Dr. Franklin W. White, Boston, was elected president, and Dr. John Bryant, 338 Marlborough Street, Boston, secretary; the next annual meeting will be at Atlantic City, May 2-3, 1927.

Homicides in 1925.—In continental United States in 1925 there were about 10,100 homicides, according to the *Statistical Bulletin* of the Metropolitan Life Insurance Company, which is fourteen times the number that would have occurred if the homicide rate of England and Wales had prevailed in this country, and six times as many as would have occurred had the homicide rate of Canada prevailed. The *Bulletin* says that in a recent year the city of Chicago alone had more than twice the number of homicides that occurred in all England and Wales. The Metropolitan Insurance Company has endeavored to discover what legal action is taken when homicides occur among its own policyholders, and has facts available in 611 homicides which occurred in 1922-1924. Deducting eighty-six "justifiable" homicides, there were 525 assailants answerable to the law; of these fifty-four committed suicide and thirteen died before they were arraigned; of the remaining 458 assailants, eighty-four had not been captured within a year after the crime was committed, and of the 374 who were apprehended, 108 were released by grand juries or magistrates, as no case could be made out against them; eight were declared insane. There were actually brought to trial 258 or 56.3 per cent of the original group of 458, and of these, 187 were found guilty, 170 being sentenced to prison, eight sentenced to death, and nine released either by a fine or on a suspended sentence.

Women's Organizations Fight for Sheppard-Towner Act.—Concentrated efforts are being made by women's national organizations throughout the country to have the Senate reject the amendment of the Senate Committee on Education and Labor to reduce the time for extension of the Sheppard-Towner Infancy and Maternity Law. The Senate committee recognized the objections made by the medical profession against the principles involved in the Sheppard-Towner Law and, in its report to the Senate, insisted that the expenditure by the federal government of more than a million dollars each year in this work should terminate, June 30, 1928. The committee further recommended that no federal funds should after that date be made available for the states to carry on this work under the arrangements in the law requiring a state to match or appropriate an equal sum from state funds to that appropriated by the federal government. This unanimous action of the Senate committee is in direct accord with the attitude of The Journal and of the medical profession generally throughout the country.

No less than ten women's organizations have pooled their interests in a national campaign of propaganda to defeat the amendment of the Senate committee. These national women's organizations include the National Board Y. W. C. A., National Council of Jewish Women, National Consumer's League, National Association of Colored Women, National Council of Women, General Federation of Women's Clubs, National League of Women Voters, American Association of University Women, National Women's Trade Union League, National Congress of Parent-Teachers, and Women's Christian Temperance Union.

Members of the Senate are receiving hundreds of letters and telegrams as a result of this combined offensive of these women's organizations. It may be that the amendment of the committee will be imperiled as a result of the political influence thus brought to bear on members of the Senate. Diligent inquiry made of various senators does not disclose the fact that physicians have written or telegraphed their senators urging that the Senate committee amendments be adopted when the bill comes before the Senate for final action. Unless senators are informed of the request of the medical profession that this amendment be retained, it is quite probable that the committee will not be able to muster enough votes in the Senate to retain the amendment in the bill in its final passage.

CANADA

Association for Study of Feebleminded.—The fiftieth annual meeting of the American Association for the Study of the Feebleminded will be held in Toronto, June 3-5, at the King Edward Hotel. The prime minister of Ontario and the mayor of Toronto will deliver addresses of welcome. Among others, Dr. Thomas J. Heldt, of the neuropsychiatric division of the Henry Ford Hospital, Detroit, will speak on "The Neuropsychiatric Importance of the Personality Reactions of Mental Defectives"; Charles B. Davenport, Ph.D., director, department of eugenics, Carnegie Institute of Washington, Cold Spring Harbor, New York, "The Nature of Hereditary Mental Defect"; Dr. Groves B. Smith, Detroit, "Cerebral Accidents of Childhood—Their Relation to the Problems of Mental Deficiency," and Dr. George K. Pratt, of the National Committee for Mental Hygiene, on "The Application of Mental Hygiene Methods to the Feebleminded." The annual dinner will be held Friday evening, when the president of the association, Dr. Arthur R. T. Wylie, superintendent, Institution for Feebleminded, Grafton, N. D., will deliver his address.

FOREIGN

Ophthalmologic Congress.—The Oxford Ophthalmological Congress will meet at Keble College, Oxford, England, July 15-17; on Thursday the discussion will be on "Sympathetic Ophthalmia"; Friday the Doyne Memorial Lecture will be delivered by Dr. Thomas Henderson on the "Anatomy and Physiology of Accommodation in Mammalia." An afternoon will be devoted to demonstrations in the scientific and commercial museums.

British Association to Publish Another Journal.—The council of the British Medical Association at its April meeting decided to publish the *Journal of Neurology and Psychopathology* as and from the issue of May, 1926. This journal was started in 1920 to take the place of the former *Review of Neurology and Psychiatry*, which was published successfully from 1903 to 1918; under the auspices of the British Medical Association, the journal should find a larger sphere of usefulness. Dr. Samuel A. Kinnier Wilson is the chief editor. The journal will appear quarterly; orders (30s.) should be sent to the Financial Secretary, British Medical Association, Tavistock Square, London, W. C. 1.

Prize for General Practitioners.—The British Medical Association will award the first "Sir Charles Hastings Clinical Prize" of 50 guineas for general practitioners to Dr. Norman Porritt of Llandudno for his clinical study on "The Abdomen in Labor." The prize will be presented to Dr. Porritt at the annual meeting of the association in July at Nottingham. There were twenty clinical studies submitted by physicians for the prize this year. The council conveyed to Sir Humphry Rolleston and Prof. W. E. Dixon an expression of appreciation and gratitude for their report on the essays submitted for this prize. The competition is announced also for 1927, and the following conditions are imposed:

1. Any member of the association who is engaged in general practice is eligible to compete for the prize.
2. The work submitted must include personal observations and experience of the candidate collected in general practice, and a high order of excellence will be expected. If no essay entered is of sufficient merit, no award will be made.
3. Essays, or whatever form the candidate desires his work to take, must be sent to the Medical Secretary, British Medical Association House, Tavistock Square, London, W. C. 1, not later than Dec. 31, 1926, and the prize will be awarded at the annual general meeting of the association, to be held at Edingburgh in July, 1927.
4. If any question arises in reference to the eligibility of the candidate or the admissibility of his essay, the decision of the council on any such point shall be final.
5. Each essay must be distinguished by a motto, and must be accompanied by an envelop marked with the same motto, and including the candidate's name and address.
6. The candidate who gains the award shall, if the council so desires, publish his paper in the *British Medical Journal* or deliver a lecture on the subject thereof at a meeting of the association.

Personal.—The fiftieth professional anniversary has recently been celebrated by the emeritus professors, H. Vierordt, Tübingen; M. von Gruber, Munich, and P. Zweifel, Leipzig.——Prof. G. Hoppe-Seyler, Kiel, son of the founder of the *Zeitschrift für physiologische Chemie*, has been made emeritus professor, as also Prof. E. J. Moure, of the chair of ear, nose and throat diseases, Bordeaux. A souvenir medal is to be presented to the latter; Dr. Junca, cours d'Alsace-Lorraine, Bordeaux, is in charge of subscriptions for the purpose.——Prof. M. Couto, Rio de Janeiro, delivered an address on "Visceral Polysteatosis" at the Paris medical school recently, and he was the guest of honor, with Professor Austregesilo, at a banquet later.——Prof. F. Müller, Munich, surprised the recent German Internal Medicine Congress by his denunciation of the "overproduction of medical articles, the inability of the younger generation to condense their articles for publication, and the lack of rigorous discrimination by the editors in selecting articles to publish."——The medical secretary of the British Medical Association, Dr. Cox, who has been in South Africa for several months in the interests of the association, returned home, April 12. Of the 1,400 medical men in South Africa, Dr. Cox is said to have seen nearly 700 of them in groups of from three to seven; he is said to have done a great organizing work.——A complimentary dinner was given to Sir Robert Bolam by the council of the British Medical Association, April 7, in order to congratulate him on the honor recently conferred by the king.——The late Dr. J. Basil Hall, of Bradford, England, past president of the British Medical Association, left an estate valued at £29,823.

Government Services

Navy Orders

Lieut. Commdr. Richard H. Miller was placed on the retired list, April 10.——Lieut. Donald E. Dement has tendered his resignation from the medical corps.——Lieuts. William E. Crooks, Thomas L. Morrow, Robert H. Snowden, Charles E. Morse and John W. Vann have qualified for promotion to the rank of lieutant commander.——Lieut. Commdr. William Chambers on completion of a course of instruction at the Naval War College, Newport, R. I., will be transferred to the Bureau of Medicine and Surgery of the Navy Department, Washington, D. C., for duty.——Lieuts. William S. Leavenworth and William D. Davis, Medical Corps, U. S. Navy, have been found qualified for promotion to the rank of lieutenant commander.——Following the graduating exercises, May 1, at the Naval Medical School, Washington, D. C., Lieut. Comdr. Robert G. Davis, on completion of his course of instruction at the Massachusetts General Hospital, Boston, will be assigned to the Bureau of Medicine and Surgery, Navy Department, Washington, D. C.——Capt. Richmond C. Holcomb, now attached to the U. S. S. *Mercy*, has been assigned to represent the medical department of the navy at the Sesqui-Centennial Exposition, Philadelphia, which opens in June.——Comdr. Frank E. Sellers, Naval Hospital, Norfolk, Va., has been assigned to the U. S. S. *Tennessee*, and Comdr. Clarence F. Ely of the U. S. S. *Tennessee* has been assigned to the naval training station, Hampton Roads, Va.

Army Personals

The resignation of Capt. Luther H. Kice as an officer of the medical corps of the army was accepted, April 24, and that of Capt. Harold O. Brown was accepted, effective, May 10.——Edward R. Weidlein, M.A., director, Mellon Institute of Industrial Research, University of Pittsburgh, and R. A. Gortner of the University of Minnesota have been appointed research consultants in the chemical warfare service of the U. S. Army.——Dr. Melvin T. Means, Claremore, Okla., first lieutenant, medical reserve corps, has been appointed first lieutenant in the regular army medical corps with rank from Jan. 9, 1926; also Dr. Harold W. Kohl, Denver, with rank from January 27, and Dr. Fritjof H. Arestad, San Francisco, with rank from January 29.

Examination for Entrance Into U. S. Public Health Service

There will be examinations, July 12, held in Washington, D. C., Chicago, New Orleans and San Francisco for entrance into the regular corps of the U. S. Public Health Service. Candidates who successfully pass an oral, written and clinical examination before a board of medical officers, and who undergo a physical examination will be recommended for appointment in the service by the President. Candidates must be not less than 23 nor more than 32 years of age, and be graduates of some reputable medical college and have one year of hospital experience or two years of professional practice. Permission to take the examination may be obtained from the Surgeon General, U. S. Public Health Service, Washington, D. C.

President Signs Bill to Retire Nurses

The President has signed a bill for the retirement of army and navy nurses. The bill places army and navy nurses on the same status, with respect to retirement privileges, as has been heretofore allowed to commissioned officers of the army and navy. It provides that after twenty-five years' service, army and navy nurses will receive 75 per cent pay; or, after reaching the age of 50, with twenty years' service, retirement pay allowance shall be 60 per cent. The peace-time strength of the nurse corps in the army and navy is approximately 500 in each of the corps. During the war the number was raised in the army to 22,000 and in the navy to 1,500. May 14, in the office of Rear Admiral Edward R. Stitt, Surgeon General of the Navy, General Merritte W. Ireland, Surgeon General of the Army, presented the pen with which the President signed the bill to Miss Anna G. Davis, assistant superintendent of the navy nurse corps. The presentation was made in recognition of the work of Miss Davis in behalf of the passage of the bill.

Foreign Letters

LONDON

(From Our Regular Correspondent)

May 1, 1926.

The Coordination of Research Libraries

The Association of Special Libraries and Information Bureaus, which has grown out of the two conferences of persons engaged in handling special information, has been formally inaugurated. The objects are to examine, foster and coordinate the activities of special libraries, information bureaus and similar services; to act as a clearing house for these services; to develop the usefulness and efficiency of special libraries and information bureaus under whatever titles they may function; and, generally, to promote, whether by conferences, meetings or other means, the adequate dissemination of systematic published information. The first work of the association will be the preparation of a directory of special libraries and information bureaus in the United Kingdom. This work, which is to be financed by the Carnegie United Kingdom Trustees, is estimated to cost about $10,000. It is hoped to arrange for mutual cooperation and assistance between institutions such as commercial houses, manufacturing concerns, newspapers, banks and insurance offices, technical and scientific societies and political, social and educational organizations, and the staffs concerned, in order to develop to the utmost the effective use of existing collections in national, public and special libraries. It is proposed to admit ordinary members and associate members at subscriptions of $10 and $5, respectively. The subscriptions will be the same for individuals as for institutions, but the committee desires that membership shall be institutional rather than individual. The association wishes to establish free trade in published information, but there will be no obligation on any librarian to supply information which he feels he is not justified in giving.

Marriage and Hereditary Deafness

That persons who are afflicted with hereditary deafness should not marry each other was one of the dicta laid down by Dr. R. Scott Stevenson in a lecture at the Institute of Hygiene. Deafness he thought more serious than blindness, for while a blind child could be educated at the ordinary schools, a deaf child could not be educated with normal children. Heredity as a cause of deafness was rather a thorny subject. Congenital syphilis was a common cause among children of the poorer classes, but it was impossible to deal with the prevention of syphilis until its notification and treatment were made compulsory. There was, however, a common form of hereditary deafness that had no relation whatever to syphilis. To prevent this type it was necessary to take a long view and to lay down the law that persons should not marry one another at all if affected by hereditary deafness, and that it would be better if these did not marry with persons with deaf relatives. It was a curious fact that the deaf tended to marry the deaf, presumably because the bond of their mutual affliction tended to bring them together, and because of the ease with which they communicated with each other.

An Airplane Medical Service

Australia may be the first country to institute a regular service of flying physicians and dentists. The national commission on health is considering a scheme by which the airplane mail lines might assist in bringing rapid medical aid to any one dangerously ill in the remote bush areas. The Australian inland mission of the League of Red Cross Societies is seeking to install a simple, standard wireless apparatus that may be worked effectively by any nontechnical possessor in the "black blocks." The railways in the six Australian colonies tap scarcely more than the eastern and southern coastal strips of a territory roughly as big as the United States, and physicians at present have to do much of their diagnosis and treatment by telegraph. Often the sick person has many miles to travel to reach a telegraph station from which he can solicit skilled advice. When he has related the symptoms and the physician has prescribed as best he can, the patient has next to find a center possessing a medicine chest. Standard drugs and simple surgical appliances are kept at the scattered repair posts and police stations, and having arrived at one of these, the sick man follows the physician's orders to the best of his intelligence. Many perplexing cases need personal examination for proper treatment, and the inland mission is mapping out districts in central Australia that could be served by physicians transported by air over areas with radii of 200 miles. A system of filling stations may be devised still further to increase the range of the flying physician.

Proposed International Society of Medical Practitioners

At a meeting of the Federal Committee of the British Medical Association in Australia, the honorary secretary read a letter from the medical secretary of the British Medical Association, intimating that at the time the new headquarters in Tavistock Square were opened, five delegates of foreign medical organizations had met informally in his office to discuss the proposal to inaugurate an international society of medical practitioners. As a result, a letter of invitation was drawn up by Dr. F. Decourt and sent to the presidents and secretaries of representative medical organizations in various countries. The object of the proposed society is to serve as an international bureau of information on matters affecting medical practice in any country. The organization would be an inexpensive one, since it would be unnecessary to appoint a council or committee. All that would be required would be a secretary and a small clerical staff in a properly equipped office.

Fatal Septicemia from Performing a Postmortem Examination

In previous letters, two cases were recently reported in which young physicians lost their lives in performing postmortem examinations. In the following case a man, only 22, of great promise, came to a similar end. He took an examination in pathology, March 18. As the youth had come without rubber gloves, the professor lent him a pair. They were perfectly sound, but after the examination the professor learned that they had been torn. He made no mention of injury. The young man was admitted to the hospital, March 22; the third finger of the left hand was incised. Despite treatment he became progressively worse, and died from septicemia, probably resulting from an injury he received while making a postmortem examination.

Arsenic on American Apples

The finding of arsenic in dangerous quantities on American apples has had a disastrous effect on their sale in the English market. The difficulty with American apples is the necessity for late spraying. There are three broods of the codling moth, and in order to destroy the pest American growers have been obliged to spray the trees when the fruit is fully formed. At home we spray only before the flower appears, and again immediately after the petals have fallen. The practice is stated to be similar with Australian growers, who find no need to spray after the apples have formed. Before the next season for American apples begins it is considered probable that some arrangement will be made, perhaps by extensive washing in the particularly dry belts which are most susceptible to contamination, to guarantee the crops to be free from arsenic. Canadian growers, many of whom have been as much affected by the scare as those in the United States, are already considering whether late spraying should not be altogether prohibited.

The British Medical Association and Nursing Homes

Evidence was given on behalf of the British Medical Association before a select committee of the house of commons, which is taking evidence on the desirability or otherwise of nursing homes being subjected to registration and inspection. The attitude of the association was stated to be that, while it was not against registration of nursing homes in principle, it was opposed to some of the provisions in the bill before parliament. It suggested that local authorities should set up special committees on which the medical profession should be represented, either by cooption or by appointment, and urged that the case sheets of patients should not be accessible to any but physicians. The association contended that no nursing-homes run by physicians should be subject to registration, nor should those attached to, or associated with, voluntary hospitals. In the case of nursing homes run by private individuals for profit, there was no control and no responsibility by any one.

The Australian Aborigines: Proposed Model Native State

A petition has been circulated among state and federal members of parliament by Colonel Genders, the originator and secretary of the South Australian movement for the creation of a large model aboriginal state in central Australia. The movement has for its object the saving of the race, which is disappearing before the advance of pastoral settlement and railway penetration, both of which seriously diminish the natural food resources of the natives. The petition urges that the model state should be eventually managed by a native tribunal with a native administrator, and have representation in the federal parliament, similar to that of the Maoris, for it is now acknowledged that the Australian blacks have considerable mental development, and are capable of learning industries. Cannibalism and cruel rites would be prohibited, but otherwise native laws and customs would operate, and whites would not be allowed to enter the model state unless duly accredited.

The Cancer Review

At a meeting of the British Empire Cancer Campaign, it was announced that the first number of a publication to be known as the *Cancer Review* of the campaign would be issued during May and would continue thereafter as a monthly publication. It would embrace monthly reports of all cancer research work being carried out throughout the world, in abstract form, and would, it was hoped, effectively link up the work of all cancer researchers.

The Prevention of Accidents

The second annual meeting of the National "Safety First" Association has been held. The home secretary, Sir William Joynson-Hicks, presided. He said that the association had made wonderful progress, particularly on the public safety side. The number of street accidents reported emphasized the need for their activities. For 1925 they were 115,473, or 17,000 more than in 1924. Fatal accidents reached nearly 4,000; 340 more than in 1924. Last year, on the average, more than ten persons were killed, and more than 300 injured, every single day on our roads. In London, however, there were twenty fewer street fatalities than in 1924. In the areas covered by their branches there had been a net decrease of fifteen in the number killed, as compared with 1924.

With reference to the industrial side of the movement, he assured the meeting of the warm support of the government. But in spite of everything that they could do in making regulations for the safety of factory organization, they would still have a majority of accidents in the country which could not be touched by regulations. The thoughtlessness of the human factor caused more than half of the accidents in our industrial organizations, and it was the human factor that they must endeavor to educate.

Sir Herbert Blain, vice president, said that during every year 750,000 people were killed or injured by accidents in this country. For the five years that had succeeded the war there were 200,000 more British people injured than there were wounded in the war itself. Those were enormous figures, and when it was realized that 75 per cent of the accidents were preventable by a little care and forethought, he believed it would be felt that the association was endeavoring to do work that was for the good of the community as a whole.

A Graduate Course in Physiotherapy

At the University of Naples, an advanced course in hydrology, electroradiology and physiotherapy was organized this year. The course is intended for physicians and graduates in chemistry and pharmacy, and more particularly for those who intend to practice medicine in sanatoriums located at mineral springs, either as physiotherapeutists or as public health officers.

Annual Meeting of the Italian Hydrologic Society

The Associazione medica idrologica italiana held its customary annual general assembly under the chairmanship of Professor Devoto, the president of the society, and Professor Piccinini, regional president of the Sezione alta Italia.

Course in Hygiene and Infant Welfare

The course in hygiene and infant welfare, the fifth to be held, was begun last month at Rome in the E. Maraini Preventorium, under the auspices of the Italian Red Cross and under the direction of Professor Valagussa.

Congress on Industrial Medicine

The Congress on Medicina del Lavoro, or Industrial Medicine, will be held at Genoa, October 12-15, and, for the first time, will be organized by the Scuola d'igiene sociale, established by the commune of Genoa in 1922. The president and secretary of the executive commitee are, respectively, Professor Ramoino and Dr. Crosa. The topics on the program are: (1) The individual conditions and changes in the organs of persons suffering from electric shock; (2) condition of health of Italian emigrants who return home; (3) vocational guidance from the medical, industrial and operative points of view; (4) microchemical and biologic reactions in relation to the industries, and (5) the workshop from the hygienic point of view.

The Prophylaxis of Smallpox

The minister of the interior is establishing more efficient prophylaxis against smallpox, and is creating registration places for the first vaccination and revaccination. In localities in which the service has not been rigorously conducted, an investigation will be instituted.

The Provincial Antituberculosis Societies

Antituberculosis societies have now been created in almost all the Italian provinces. The minister of the interior has set forth the duties of the societies. Their activities should be sustained, and, when necessary, given financial aid, by the provincial administrations. As campaign centers, the societies are urged, above all, to organize antituberculosis dispensaries, which ferret out tuberculous patients, assist them, and inform them of the institutions where they may receive aid. The work of the dispensary should be supplemented by that of visiting nurses who go to the homes and the working places of the sick. For the recovery of patients the societies should endeavor to have available a sufficient number of beds in care-taking centers. At the same time, the societies should promote preventive and prophylactic work. The establishment of homes for infants, permanent rural colonies, open-air schools, work and school colonies, and the placement of predisposed infants, carefully selected, in healthy rural families (the Grancher system), will aid in the accomplishment of the ends desired. The societies should give particular care to sanitation in the home, and should promote the construction of sanitary dwellings for the working classes. Finally, a publicity campaign should be launched for the education of the masses in hygiene by means of motion pictures, lectures, tracts, and by the establishment of an "antituberculosis day" and of a "flower festival."

The Centenary of Francesco Redi

February 18, was celebrated the tercentenary of Francesco Redi—physician, poet and naturalist—who remains today one of the most typical prototypes of Italian science of the seventeenth century. Physician to the grandducal court of Florence, his views, as handed down by contemporaries, show him to have been a keen observer and an excellent diagnostician. He was the first to demonstrate that the venom of snakes is not active if administered by the gastric route. He asserted the therapeutic value of quinine against the opinions of physicians of his time. He taught that simplicity in therapy is a precious quality, and many of his recommendations are applicable today.

Antivivisection Propaganda

The Association for the Prevention of Cruelty to Animals intends to ask for the passage of a law limiting vivisection. Its reports show complete ignorance of working methods of biologic laboratories; for instance, of the fact that anesthesia is employed in all experiments, and that strict surgical technic is applied when survival of the subject is expected. One of the views advanced is that the only experiments justified are those intended to determine some unknown or doubtful question, since after certain knowledge is acquired, repetition of the experiment involved is merely cruel or abusive. This demonstrates absolute disregard of the fact that a question is never closed and that experimental work is essential for medical teaching. Let us hope that this new campaign will not harm scientific research.

Assault on a Professor

The agitation that gradually has spread among university students, since they secured an electoral share in university management, has reached such extremes that some undergraduates, especially the most inefficient ones, devote practically all their time to school politics. The many concessions of the governing bodies have been dexterously exploited by the students, who now can present themselves for examination every three months, and any number of times. Many of them have thus been rejected as many as ten consecutive times. Until a short time ago, the third (and then the fourth) failure automatically caused dismissal of the student. Of late, however, those failing seem to blame the examining board for their misfortune. In the last four or five years, the custom has prevailed of sending offensive or threatening anonymous letters to any professor who fails students. Such conditions reached a climax when Prof. B. A. Houssay was hit from behind with an iron bar. In addition to a wound in the temporal region, a fracture of the right hand was caused. An inquiry showed that the crime had been instigated by a 40 year old student, who had been held back several times, who has a police record, and who has been connected with several disturbances in the medical school. This outrage caused indignation among both the teaching staff and the student body. The faculty members signed a protest, and disciplinary measures are expected on the part of the dean and governing board.

Hospital Enlargement

The new buildings of the Salaberry Hospital, on which the city authorities have spent 4,000,000 pesos (about $1,600,000), have just been opened. The new services include surgery, obstetrics and gynecology, pediatrics, administration and dietetics. The new orthopedic, laryngology and ophthalmology departments, and the morgue and kitchen pavilions, of the Pirovano Hospital will be finished next month. The cost will be 800,000 pesos (about $320,000). April 12, the Rawson Hospital, after a complete reconstruction, will be thrown open to the public. This hospital will have 1,800 beds, one of the largest hospitals here.

Personal

Prof. G. Fichera of Pavia has taken charge of a surgical pathology class, under Prof. Arce.——Dr. A. Ceballos, assistant professor of clinical surgery, has gone to the United States, to study conditions there, and present his arthroplasty work.——Prof. M. R. Castex has given a number of lectures in Germany and has met with a favorable reception.——The following have just returned from Europe: Dr. E. Hug, after completing some studies in physiology at Turin and Berlin; Dr. G. A. Castaño, assistant professor of gynecology; Dr. E. Mariño, assistant professor of medical pathology, and Dr. Inda, who took a course in epidemiology at Hamburg.

VIENNA

April 13, 1926.

The Retirement of Professors Riehl and Dimmer

With the end of the summer semester, the so-called *Ehrenjahr*, or honor year, which was granted Professor Riehl the director of the First Dermatologic Clinic at the University of Vienna, comes to a close. Professor Riehl is past 70 years old, and is compelled by the law requiring retirement of university professors at the age of 70 to give up his post. His enforced resignation awakens many regrets that the retirement law should prevent such eminent men as Riehl from continuing their activities. The situation is made worse by the fact that the natural successor to Riehl, the Vienna dermatologist Professor Kyrle, died, some time ago, quite unexpectedly. Concerning the fate of the First Eye Clinic, of which Prof. Dr. Dimmer, recently deceased, was the director, no definite action has been taken as yet. At first it was reported that for economic reasons the clinic was to be closed. However, the united protest of academic circles, and certain keen-sighted government officials, succeeded in frustrating any such designs. Scarcity of funds, however, makes difficult the execution of plans.

Care of the Tuberculous in Austria

In a recent number of the official *Mitteilungen des Volksgesundheitsamtes*, there appeared a report, edited by Dr. Eisenschimmel and Director Lukesch, on the present status of the tuberculosis care-taking centers in Austria, and giving an account of their activities in 1925. The report reveals that there are only fifty-nine tuberculosis care-taking centers in operation. These serve only one fifth of the territory to be covered, and provide for approximately half of the total population. Each center must care, on the average, for about 62,000 persons. During 1925 more than 1,500,000 persons appeared at the centers for consultation. Of new patients, 11 per cent, or 3,279, proved to be seriously ill. One of the chief tasks undertaken by the care-taking centers was to minimize the spread of infection. As high as 70 per cent of the members of families exposed have been found to be tuberculous. Nurses of the care-taking centers found that of 5,294 cases the patient shared his bed in 2,836 cases with other adults and in 2,458 cases with children. In more than 40 per cent of the cases, there were, besides the patient, three constant occupants of the living room; in 23 per cent of the cases, there were four other occupants, and in only 7 per cent was the patient associated with only one other person. In 8 per cent of the cases, the dwelling consisted of more than two rooms; in 35 per cent, of two rooms; in 46 per cent of only one room, and in 11 per cent, two or three families lived in one room. By the efforts of the care-taking centers, 7,648 patients were provided beds in institutions in which they received medical treatment; 3,763 were placed in homes for convalescents, and 28,942 persons were examined or assisted.

The Sanitary Conditions of Vienna, Winter of 1925-1926

Health conditions in the capital for October to March were favorable up to about the middle of February. The weather was cold and dry during December and January. In February, an epidemic of influenza set in. There was, therefore, an increase of mortality in March, which is still observable in April.

The Value of the Bacteriologic Examination in Trachoma

At a recent session of the Vienna Ophthalmologic Society, Dr. Pillat presented a paper in which he discussed his microscopic researches in thirty-eight cases looking toward clarification of the diagnosis of trachoma. The difficulty of differentiating conjunctivitis follicularis from trachoma by clinical methods alone should give the bacteriologic examination greater importance. During an epidemic, Pillat observed among 200 children examined fifty-eight suspicious cases, in thirty-eight of which he made microscopic examinations. Of these, thirty-five, or 92 per cent, showed typical trachoma inclusions, whereas three cases in which the clinical manifestations pointed to trachoma showed no cell inclusions. Clinically, the thirty-eight positive cases were, in part, moderate and, in part, very mild, so that it was impossible to differentiate them otherwise from ordinary cases of follicular catarrh. Follicles were present in almost all of them; in 88 per cent, the conjunctiva bulbi was not affected, the cornea was never involved, and the secretion was slight. In four cases, the inclusion bodies were exceedingly numerous; in thirteen cases, there were from ten to forty inclusion bodies; in ten cases from two to ten, and in seven cases only one inclusion body. In fourteen cases, several (as high as six) preparations had to be prepared.

BELGIUM

The New Law Pertaining to Occupational Diseases

A new type of service in factories has been organized, which is intended more particularly for industries in which toxic substances such as lead and zinc are handled. It includes the installation of sanitary equipment and supplies, and a complete medical service. No charge will be made for the use of the equipment. The heads of industries will entrust the regular inspection of employees and the sanitary equipment of their factories to physicians approved by the minister of labor. They will keep a register showing the names of workmen who have been absent on account of sickness; also the dates and the duration of such absences. The physicians will inspect the sanitary condition of the factory equipment at least once a month. They will question (without compelling them to leave their posts) those workmen who appear to be failing in health. After each of their inspections, the physicians will make a written report of observations in special registers, but will exclude information involving professional secrecy. On their general visits, the physicians will examine more particularly: (1) workmen who present symptoms that may be due to occupational disease; (2) workmen who show recurrence of such symptoms in two months after the symptoms have been made to disappear; (3) workmen who have been absent from work on account of sickness, since the last visit of the physician; (4) workmen whose health appears doubtful, and (5) workmen who request such examination. They will record their findings on cards to be supplied by the heads of industry. The employers will, through their physicians, institute a general revision of the personnel of their establishments whenever they are requested so to do by the chief inspector of mines, or by the medical inspector of labor. The employers or managers will pay all the costs of medical inspections, and deductions will not be made from the wages of workmen for loss of time incurred by such inspections. Records will be preserved for at least five years. The registers will be open to examination by government inspectors charged with the execution of the law.

The law contains also provisions pertaining to general hygiene and industrial organization. For the better taking of samples of fumes and residual gases, shuttered openings will be provided at easily accessible points in the walls of chimneys or other conduits for the evacuation of fumes. Devices will be installed to carry off fumes, to dilute the gases thrown off by the ovens, and, as far as possible, to effect the condensation of harmful material.

Welfare Work in the Belgian Congo

The Union coloniale belge has responded to the appeal of the colonial minister and has organized special courses on the prophylaxis of malaria and trypanosomiasis. The directors of the great enterprises concerned have supported the initiative of the Union coloniale belge, and have required all their agents to take part in the course. The movement is one of the surest means of accomplishing results in the crusade against tropical diseases.

A New Publication

A new monthly review that has been launched in Belgium is called the M. I. L. review and deals with the financial interests of the medical profession. The device of the new publication is: *nummis potiri quam servare facilius* (it is easier to make money than it is to keep it).

The Sterilization of Criminals

Before the Société belge de médecine légale, M. Vervaeck discussed recently the question of sterilization of certain criminals. Sterilization has been advised in cases of hereditary mental disease (dementia praecox, cyclothymia), in the markedly weak-minded (sterilization before puberty); in psychopaths, constitutional epileptics; in incurable toxicomania, and sexual perverts. In all these cases, our knowledge is not sufficiently exact to justify sterilization.

The Queen Elizabeth Foundation

The Queen Elizabeth Foundation is the realization of a project which had its beginning during the war. The queen had observed that the hospitals on the Belgian front were, in truth, medical schools. She expressed the desire that, at the conclusion of the war, there might be founded in Belgium a medical institute in which the activities of the hospitals of the Belgian front might be continued. Such an institute was conceived of as a combination of hospital services and research laboratories. By creating laboratories of all the auxiliary sciences of therapeutics, and by inviting all those interested in research and in new methods to attend the institute, all resources of science could be mobilized against disease. With the collaboration of the Rockefeller Foundation, the laboratories of the queen have been installed temporarily in the hospitals of Brussels under the directorship of Professor Nolf.

Industrial Diseases in Relation to Accident Insurance

A decree issued by the federal government, July 1, 1925, provides that not only industrial accidents shall come under federal accident insurance but also such affections as develop owing to industrial injuries and which extend over long periods and are almost imperceptibly cumulative. Advances in medical knowledge of the last decade have furnished the bases for decisions as to the significance and the origin of many occupational diseases. The decree, however, concerns only such industries as come within the scope of federal industrial accident insurance. The new insurance extends, furthermore, only to the diseases that are enumerated in the decree. References to these diseases in the decree are entirely general; for example, we read that industries in which "affections caused by lead, phosphorus, mercury, arsenic, benzene, carbon disulphide, roentgen rays and other forms of radiant energy occur" are compensatable industries. Although such comprehensive designations may open the way to controversy, on the other hand, trade unions and the courts can adapt themselves to changing views of medical science. The connection of an affection with employment in a recognized industry must be shown. The insurance bureau must in all cases have the person who is ill examined by a suitable physician. The decree introduces the so-called *Uebergangsrente*, or temporary benefit. In many of the dangerous industries, the workmen must subject themselves to periodic medical examination. If an insured workman shows signs of an incipient industrial disease, continuance in his employment is often hazardous. However, the workman may not be able to give up this work, for financial reasons. In such cases, the employer may be expected to grant the workman a temporary benefit up to half the amount of the full benefit, on condition that he consent to give up his dangerous employment.

Proposed State Aid for Hospital Patients

The lack of hospital beds in Berlin, and the decreasing number of paying patients in hospitals, have brought up the question of possible changes in hospital provisions for patients of limited means. Professor Gottstein suggested, in a recent address, charging the patients, including those insured in the *Krankenkassen*, for board and room only, and imposing the remaining charges on the city. Gottstein added that, under such a provision, private charitable institutions would have to be protected in some way. Dr. Goldmann suggested that to care for patients who do not need the expensive equipment of the modern hospital, "mild patients hospitals" and caretaking homes might be erected. Goldmann demands further extension of the domiciliary care of patients, a form of service which heretofore has been in the hands of private welfare societies. The domiciliary care of patients relieves greatly the demands on the hospitals. Evidence of the popularity of domiciliary care supplied by the state is furnished by the facts that in 1925 the Evangelisch-Kirchliche Hilfsverband (auxiliary of the Protestant churches) provided domiciliary care for 27,000 patients and the Katholische Charitas-Verband similar care for 34,000 patients in Berlin. In the discussion that followed, objections were raised to Gottstein's demands on the grounds that the cost would be too great.

Marriages

Rolla L. McCreery, Torrington, Wyo., to Mrs. Frances Ramsey of San Francisco, at Sidney, recently.

Albert B. Murphy, Everett, Wash., to Miss Vesta Kruse of Rochester, Minn., at Ellensburg, recently.

Henry G. Mealing to Miss Lillie May Glover both of Augusta, Ga., March 21.

Deaths

Charles Edward Elliott, Victor, Colo.; University of Vermont College of Medicine, Burlington, 1888; University of Bishop College Faculty of Medicine, Montreal, Que., Canada, 1889; member of the Colorado State Medical Society; for many years mayor of Victor; member of the state legislature; served during the World War; aged 60; died, April 18, of pneumonia.

George Augustus Peck ⊕ New Rochelle, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1891; member of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons, and of the American Urological Association; on the staff of the New Rochelle Hospital; aged 59; died, April 23, at Milan, Italy.

John Joseph Mahoney, Jamestown, N. Y.; Niagara University Medical Department, Buffalo, 1896; member of the Medical Society of the State of New York; for twenty years superintendent of public health of Jamestown and for twelve years district state sanitary supervisor; aged 57; died, April 18, of heart disease.

Franklin Freese Lehman, Sandusky, Ohio; University of Michigan Homeopathic Medical School, Ann Arbor, 1891; member of the Ohio State Medical Association; past president of the Erie County Medical Society; for several years county coroner; aged 64; died, April 23, of chronic myocarditis and arteriosclerosis.

Charles Lawrence Orr, Pratts Fork, Ohio; Physio-Medical College of Indiana, Indianapolis, 1891; member of the Ohio State Medical Association; aged 56; died, April 29, at the Athens (Ohio) State Hospital, of cerebral hemorrhage.

Lewis W. Flinn, Wilmington, Del.; Jefferson Medical College of Philadelphia, 1883; Hahnemann Medical College and Hospital of Philadelphia, 1887; on the staff of the Homeopathic Hospital; aged 67; died, April 4, of heart disease.

Lanta Weirick Ford, Syracuse, Ind.; Medical College of Indiana, Indianapolis, 1901; member of the Indiana State Medical Association; aged 51; died, April 9, at the Elkhart (Ind.) General Hospital, of nephritis.

Joseph Howard Langworthy, Leavenworth, Kan.; University of Pennsylvania School of Medicine, Philadelphia, 1907; served during the World War; aged 46; died, March 30, of thrombosis of the coronary arteries.

James Crawford Watson, Georgiana, Ala.; University of Alabama School of Medicine, Tuscaloosa, 1898; member of the Medical Association of the State of Alabama; aged 50; died, March 15, of acute nephritis.

Willard S. Cushman ⊕ Baton Rouge, La.; Medical Department of the Tulane University of Louisiana, New Orleans, 1900; for fourteen years parish coroner; aged 50; died, March 6, of chronic nephritis.

Emory Hale Connelly, Alberta, Va.; University College of Medicine, Richmond, 1905; member of the Medical Society of Virginia; aged 43; died, March 18, of hemorrhage due to a self-inflicted wound.

Herman Nathaniel Cohen ⊕ New Albion, Iowa; Barnes Medical College, St. Louis, 1908; superintendent of the New Albion Hospital, where he died, March 27, of chronic nephritis, aged 38.

William Edward Whitford, De Peyster, N. Y.; University of Vermont College of Medicine, Burlington, 1878; aged 70; died, March 27, at the Hepburn Hospital, Ogdensburg, of heart disease.

Ulysses Augustus Rice, Des Moines, Iowa; King Eclectic Medical College, Des Moines, 1888; aged 82; died, April 10, at the Methodist Hospital of hypertension and cerebral hemorrhage.

Charles Henry Moore ⊕ Albany, N. Y.; Albany Medical College, 1887; on the staffs of the Child's, Albany and St. Margaret's hospitals; aged 68; died, February 13, of chronic myocarditis.

Augustus Francis Schafer ⊕ San Francisco; Bellevue Hospital Medical College, New York, 1887; aged 61; died, April 29, at the Stanford Hospital, of carcinoma of the stomach.

Alexander R. Shadden, San Augustine, Texas; Vanderbilt University Medical Department, Nashville, Tenn., 1892; Confederate veteran; aged 76; died in April, of chronic bronchitis.

Harold Edwards Bates, Portland, Ore.; Johns Hopkins University Medical Department, Baltimore, 1915; served during the World War; aged 37; died, March 30, of tuberculosis.

William Cady Fawdrey, Lorraine, N. Y.; Albany Medical College, 1885; member of the Medical Society of the State of New York; aged 65; died, April 21, of erysipelas.

Fred B. McGarvey ⊕ Cavour, S. D.; University of Tennessee College of Medicine, Memphis, 1900; aged 57; died, March 19, at Highmore, of pulmonary tuberculosis.

Nathaniel Saenger, St. Louis; Missouri Medical College, St. Louis, 1895; served during the World War; aged 53; died, April 28, of melanosarcoma of the scalp.

August Ferdinand Schoen, Mayville, Wis.; Rush Medical College, Chicago, 1883; aged 75; died, March 2, at the Beaver Dam (Wis.) Hospital, of senility.

Ellen Eastman Schenck, Ashby, Mass.; Boston University School of Medicine, 1880; aged 70; died, April 19, at a hospital in Luenburg, of paralysis agitans.

Stephen M. Applewhite, San Antonio, Texas; Medical Department University of Louisiana, New Orleans, 1875; aged 73; died, March 2, of pneumonia.

Alfred M. Michaelis, New York; Cornell University Medical College, New York, 1925; intern, Mount Sinai Hospital; aged 24; died, April 24, of septicemia.

Harry Neville Goff, San Diego, Calif.; McGill University Faculty of Medicine, Montreal, Que., 1893; aged 66; died suddenly, April 6, of heart disease.

Sterling P. Stowers, North Kansas City, Mo.; St. Louis College of Physicians and Surgeons, 1889; aged 64; died, April 21, at Sedalia, of pneumonia.

Alexander T. King, Milwaukee; Chicago Medical College, 1881; member of the Colorado State Medical Society; aged 74; died, March 29, of pneumonia.

James Aloysius Dardas, Bay City, Mich.; Northwestern University Medical School, Chicago, 1909; aged 42; died, April 19, of cerebral hemorrhage.

Charles McKenzie Hay, Atlantic City, N. J.; University of Pennsylvania School of Medicine, Philadelphia, 1888; aged 59; died, March 8, of influenza.

John H. Crowe ⊕ Virginia, Minn.; Rush Medical College, Chicago, 1901; for twelve years city health officer; aged 58; died, April 17, at Minneapolis.

Hamilton Rush Riddle, Mechanicsburg, Ill.; Rush Medical College, Chicago, 1873; Civil War veteran; aged 84; died, April 17, of bronchopneumonia.

John Desmoines Cleveland, Merrill, Ore.; Northwestern Medical College, St. Joseph, 1892; aged 66; died, March 1, of injuries received in a fall.

George Miller, Richwood, Ohio; Cincinnati College of Medicine and Surgery, 1873; aged 78; died, April 26, at his home in Byhalia, of senility.

James McManus, Lindley, N. Y.; College of Physicians and Surgeons, Baltimore, 1885; aged 66; died, January 5, of pulmonary tuberculosis.

John S. Jordan, Indianapolis; Indiana Eclectic Medical College, Indianapolis, 1887; Civil War veteran; aged 80; died, April 17, of heart disease.

Frank M. Baldwin, Columbus, Ohio; Eclectic Medical Institute, Cincinnati, 1888; formerly a druggist; aged 83; died April 21, of senility.

Herman Goodman, Chicago; University of Berlin, Germany, 1881; aged 70; died, April 1, of chronic interstitial nephritis and myocarditis.

Thomas V. Cahall, Frederica, Del.; Jefferson Medical College of Philadelphia, 1874; aged 74; died, March 14, of cerebral hemorrhage.

Thomas J. McGowen, Vincennes, Ind.; Bellevue Hospital Medical College, New York, 1882; aged 72; died, April 16, of cerebral hemorrhage.

H. E. Keller, Decatur, Ind.; Curtis Physio-Medical Institute, Marion, Ind., 1894; aged 52; died, February 22, of carcinoma of the stomach.

Felix Kalacinski ⊕ Chicago; College of Physicians and Surgeons, Chicago, 1898; aged 52; died, April 15, of carcinoma of the liver.

George D. Lain ⊕ Sanger, Texas; University of Louisville (Ky.) School of Medicine, 1892; aged 64; died, April 18, of heart disease.

Baron D. Bishop, Monticello, Miss. (licensed, Mississippi, 1882); for many years member of the school board; aged 74; died, March 30.

James H. F. Prentiss, Gary, Ind.; American Medical College, Indianapolis, 1896; aged 67; died, April 18, at St. Mary's Mercy Hospital.

Peyton Smith Pope, Benton, Ill.; University of Tennessee College of Medicine, Memphis, 1877; aged 75; died, in April, of pneumonia.

John Shibley, Gentry, Ark.; Rush Medical College, Chicago, 1886; aged 77; died recently, of hemorrhage, due to gastric ulcer.

E. W. Davis, Lavaca, Ark.; Memphis Hospital Medical College, 1901; aged 57; died, February 1, of carcinoma of the stomach.

James J. A. Edwards, Yeager, Okla.; University of Tennessee College of Medicine, Memphis, 1891; died recently, of paralysis.

George W. Crapo ⊕ Terre Haute, Ind.; Medical College of Ohio, Cincinnati, 1875; aged 73; died, April 23, of cerebral hemorrhage.

Oscar Emmett Gourley, Bado, Mo.; Northwestern Medical College, St. Joseph, 1890; aged 61; died, April 16, of pneumonia.

Megerdich Attarian, Suffern, N. Y.; Medical Department of the University of the City of New York, 1885; aged 72; died, March 11.

James W. Parker ⊕ Gray, Ky.; University of Louisville School of Medicine, 1894; aged 58; died, April 21, of nephritis.

Newton R. Baldwin, Coldwater, Mich.; University of Michigan Medical School, Ann Arbor, 1875; aged 73; died, April 20.

Robert G. Davis ⊕ Hot Springs National Park, Ark.; Jefferson Medical College of Philadelphia, 1901; aged 54; died, April 9.

Patrick Jerome Flynn, Plattsmouth, Neb.; Creighton Medical College, Omaha, 1899; aged 51; died, April 6, of pernicious anemia.

Fleming L. Phillips, Portageville, Mo.; University of Louisville School of Medicine, 1892; aged 55; was shot and killed, May 1.

William Robert Peters ⊕ Stanton, Neb.; Rush Medical College, Chicago, 1904; aged 49; died, April 16, of pneumonia.

William J. Zinn, Sherman, Ky.; Medical College of Ohio, Cincinnati, 1857; aged 95; died, April 21, of heart disease.

Charles Wesley Bond, Chicago, Rush Medical College, Chicago, 1925; aged 26; died, April 25, of pneumonia.

William D. Valentine, Spokane, Wash.; Physio-Medical Institute, Cincinnati, 1881; aged 74; died, March 20.

Eston B. Stephenson, Charleston, W. Va.; University of Louisville School of Medicine, 1897; died, April 17.

Jasper Franklin Bryant, Louisville, Ky.; Louisville Medical College, 1885; aged 62; died, April 20, of uremia.

James Alvin Minor, San Antonio, Mo.; Ensworth Medical College, 1885; aged 62; died, April 20, of uremia.

Charles Bauer ⊕ Philadelphia; Jefferson Medical College of Philadelphia, 1884; aged 83; died, April 23.

Sydney G. White, Warsaw, Ind.; Baltimore Medical College, 1893; aged 61; died, April 10, of nephritis.

Sarah M. Siewers, Massillon, Ohio; Electic Medical Institute, Cincinnati, 1891; aged 71; died, April 22.

The Propaganda for Reform

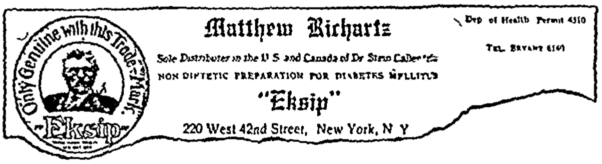
In This Department Appear Reports of The Journal's Bureau of Investigation, of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other General Material of an Informative Nature

EKSIP FOR DIABETES

A Vicious Piece of Mail-Order Quackery

One Matthew Richartz of New York City is exploiting the sufferer from diabetes in the sale of a nostrum known as "Eksip." Richartz' story is that "the noted Stein-Callenfels, the European specialist," after a life-long study, "amazed other European specialists with his famous discovery," the cure for diabetes known as Eksip. All of which is, of course, sheer buncombe. Richartz says further that his brother was closely connected with this famous individual, and, following Stein-Callenfels' sudden death, the formula of Eksip was turned over to the brother of Matthew Richartz, who has made Matthew the sole proprietor and distributor in America.

The advertising slogan for Eksip is: "No More Dieting! No More Starving! Eat And Get Well!" Richartz gets in touch with his victims, as is usual in mail-order quackery, through the willingness on the part of certain newspapers to share in the profits of quackery. Diabetics are urged to write for a booklet entitled "Eat and Get Well," which Richartz sends to anyone who asks for it. The booklet contains certain banalities, and quotations from standard works are so presented as to lead the reader to surmise that men like Ruhräh, Friedenwald and von Noorden oppose dieting in the treatment of diabetes. The booklet shows further that the only treatment for diabetes that has proved satisfactory is Eksip, and "in connection with the use of this preparation, no system of diet is given." However, the claims in the newspaper advertisements that lead the sufferer to suppose that he can eat what he likes and as much as he likes, if he takes Eksip, are not sustained in the "Eat And Get Well" booklet. There the victim is told that it is to his own interest "to avoid eating things high in percentage of carbohydrates" until after Eksip has cured the diabetes! The letter, however, which goes with the booklet, contains the following paragraph:



Only Genuine with this Trade-Mark
Eksip

Matthew Richartz
Sole Distributer in the U S and Canada of Dr Stein Callen'fels
NON DIETETIC PREPARATION FOR DIABETES MELLITUS
"Eksip"
220 West 42nd Street, New York, N Y

Dep of Health Permit 4510
Tel. Bryant 6161

> "The Eksip treatment has produced almost unbelievable results during the short time it has been used in this country. Nothing ever known to medical science has proved such an astounding success in making diabetics well. All diet list theories have been smashed — knocked to smithereens. *It is now possible, thru the Eksip discovery, for diabetics* to cast aside all restricted diet programs, and starvation absurdities, eat those foods that are necessary for strength and normal functioning of the body, and become free from sugar."

Eksip comes in tablet form—200 to a bottle. One bottle, for which $6 is charged, comprises a "full treatment." With the treatment come directions, and again the diabetic finds that the advertising claim that the diabetic can "cast aside all restricted diet programs," is hedged about with qualifications. In the "Directions" he is warned not to "overload the system with bread, potatoes, and other high carbohydrates," and he is told that the best thing to do is to "leave them alone until your diabetic condition has disappeared." Furthermore, the diabetic is warned, *after* he has purchased the nostrum, that he should not abandon the diet to which he has been used: "The best course to follow is to wait two or three weeks before changing your diet, so as to give the tablets a chance to take effect."

Of course, no information is given regarding the composition of Eksip; the question of composition is lightly dismissed with the general statement that Eksip is a "palatable compound prepared from freshly gathered herbs and plants," and that it is "based on Dr. Stein-Callenfels secret formula." There is the usual farrago of testimonials common to the mail-order quack, purporting to be from patients who are alleged to have been cured. Richartz' booklet contains what purport to be two testimonials of physicians—one from Dr. Edmund Kolb, New York City, and the other credited to Dr. A. Francis Briggs, Long Island City, New York. Dr. Kolb was born in 1855 and died in March, 1925. He was not a member of his local society. Dr. Briggs was licensed in New York in 1907 as a graduate of the Long Island College Hospital for 1904. He is not a member of his local society.

Four years ago the A. M. A. chemical laboratory made a preliminary examination of some specimens that were sent in and claimed to be Eksip. At that time the laboratory reported that the bulk of the tablets consisted of magnesium carbonate and starch, with a small quantity of an unidentified drug. Recently, because of the number of inquiries which The Journal has received relative to this nostrum, it was decided to subject the stuff to a more complete analysis, and an original bottle of "Eksip" was purchased and submitted to the A. M. A. chemical laboratory for examination. The laboratory reported as follows:

LABORATORY REPORT

"One original bottle of Eksip (Matthew Richartz, New York, N. Y.) was submitted to the A. M. A. chemical laboratory for examination. The bottle contained 200 tablets of a gray color, odorless and almost tasteless; the average weight of each tablet was 0.23 Gm. (approximately 3.6 grains). The only clew to composition given in an accompanying pamphlet was: '. . . "Eksip"—(which is a combination of simple and harmless herb and root extracts) . . .' Qualitative tests indicated the presence of magnesium, a trace of calcium, carbonate, extractive material of vegetable origin, and an acid insoluble substance resembling talc. Magnesium was present as the basic carbonate. Under the microscope, the starch grains appeared to be those of Bermuda arrowroot. Alkaloids, heavy metals, organic acids, or emodin bearing drugs were not found.

"Quantitative determinations yielded the following:

"Magnesium carbonate (calculated from magnesium oxide)	84.8 per cent
"Starch	6.9 per cent
"Acid insoluble material	6.2 per cent
"Undetermined (by difference)	2.1 per cent
	"100.0

"From the foregoing it may be concluded that 'Eksip' contains essentially magnesium carbonate and starch."

It is to be hoped that the overworked fraud-order branch of the Post Office department will before long get around to this dangerous piece of quackery.

Correspondence

TETANUS

To the Editor:—In an article in the May issue of the *Archives of Surgery,* I have called attention to the great value of treating tetanus by large doses of serum intravenously. It is recommended that intraspinal injections be given up entirely, as they would seem to increase the mortality rate.

If the tables published mean what they seem to mean, this is a very important matter in the treatment of this disease. It is, however, desirable that a large number of additional statistics should be collected. I would therefore much appreciate it if any physician who employs this method of large doses by vein to the exclusion of spinal treatment would report the facts at once so that another statistical study can be published later.

J. M. Wainwright, M.D.,
912 Clay Avenue, Scranton, Pa.

"CONTROLLING THE ODOR AND TASTE OF ARSPHENAMINE"

To the Editor:—In The Journal, March 20, Stokes called attention to his observation that the disagreeable odor and taste of the arsphenamines, when given intravenously, may be overcome by the use of a wafer containing wintergreen or clove. I imagine that Dr. Stokes' patient used a "life saver" such as are sold at the corner drugstores. This expedient was apparently helpful.

In The Journal, May 1, Broeman calls attention to the fact that good results were obtained by having his patients smell a cotton plug moistened with bay rum. Both of these are inexpensive, easily carried out and apparently effectual.

No doubt there are other methods, the descriptions of which might tax the allotted space in The Journal. Will you please allow me to inform the readers of this column that an efficient and economical way of controlling such disagreeable effects of the arsphenamines is to have the patient hold the nose and breathe through the mouth, from the time immediately preceding the injection until after the injection is finished. With the nostrils closed, air will not play over the nasal mucous membrane and disagreeable effects are avoided. While Dr. Broeman has used his method for ten years, I can say that this method has been useful for similar purposes from time immemorial.

Joseph H. Barach, M.D., Pittsburgh.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

REMOVAL OF MERCUROCHROME STAINS

To the Editor:—Is there any preparation that will remove the stains of merchurochrome-220 soluble from the hands and linen?

W. E. K., M.D., Sunbury, Pa.

Answer.—The full directions for the removal of mercurochrome as well as acriflavine stains was discussed in these columns, Dec. 6, 1924, page 1866. Because of the large number of inquiries received, the directions are again given.

According to New and Nonofficial Remedies, 1924, "the aqueous solution [of mercurochrome] stains the skin red, but the discoloration may be removed by washing in a solution of sodium hypochlorite (solution of chlorinated soda)."

The A. M. A. Chemical Laboratory reports that mercurochrome, acriflavine and other like stains can often be removed according to the following general procedure: The stained cloth is immersed in as small an amount as possible of a solution containing about 1 per cent of hydrochloric acid (1 part of diluted hydrochloric acid U. S. P. and 9 parts of water) and 2 per cent of potassium permanganate. The cloth should remain in this solution not longer than one minute; it is then transferred without rinsing to a solution containing not more than 1 per cent of hydrochloric acid, to which from 5 to 15 per cent (by volume) of solution of hydrogen peroxide, U. S. P., has been added. As soon as the potassium permanganate has been reduced by the hydrogen peroxide, the cloth is *well* rinsed in water. If the stain has not been entirely removed, the procedure is repeated, the cloth being permitted to remain in the acid potassium permanganate solution for a somewhat longer period.

Before trying the method on cloth, however, it is advisable, if possible, to subject a remnant of the unstained material to the same procedure in order to determine (1) whether or not the cloth will withstand the treatment, and (2) in the case of dyed goods, whether or not the original color is removed. In the case of fresh stains of mercurochrome, or acriflavine on dyed cloth, the former, not being fixed, can often be removed without affecting the original color of the cloth.

Stains on the hands can readily be removed by the use of the solutions just described.

PROTECTING THE HANDS AGAINST GASOLINE AND NAPHTHA

To the Editor:—Will you please give me the information concerning the possibility of protecting the hands against gasoline or naphtha gas? Workers in dry cleaning establishments find it necessary to put their hands in gasoline many times during the day, and recently there have come under my observation several cases of dermatitis from the gasoline or cleaning fluid, with secondary infections developing in the skin. Rubber or leather gloves are not practical.

Willard D. White, M.D., Minneapolis.

Answer.—Protection for the hands against the action of naphtha and gasoline is secured with greater difficulty in the dry cleaning industry than in such others as painting. This is due to the fact that it is not practical to use oily applications for the hands, for fear that the garments being cleaned may come in contact with these oily substances.

A prime factor in the production of this dermatitis, and in paving the way for secondary bacterial or fungus infection, is the de-oiling of the skin by the naphtha, gasoline or benzene. On this account the application of some bland oily material, such as hydrous wool fat or oil of theobroma, is called for. Protection for most workers may be brought about by the following steps: thorough cleansing of the hands and arms at the end of the work period with a soap that lathers freely. Immediately afterward the hydrous wool fat or oil of theobroma should be rubbed into the skin of the hands and forearms thoroughly. The application of oily material should be repeated in the morning, and once or twice during the day if the circumstances of work warrant. Some workers become so susceptible as to require a change of occupation. At the first indication of the dermatitis, the worker should be taken away from exposure to the irritants and should be treated with a weak solution of aluminum acetate. If the condition is severe, the use of aluminum acetate for three or four days should be followed with applications of zinc oxid, 10 per cent, in olive oil.

There are also on the market certain proprietary preparations for protecting the hands against gasoline and oil, particularly in garages. These appear to consist of a substance resembling a soap such as is present in chloramine surgical cream or paste. Just how efficient these preparations are in industrial use, we do not know.

GLUCOSE BRAIN BROTH

To the Editor:—Kindly send me the formula for glucose brain broth-Rosenow.

Charles Hewson Canning, M.D., Atlantic City, N. J.

Answer.—The question was referred directly to Dr. Rosenow who replies:

Two mediums, dextrose brain broth and soft dextrose brain agar, have been found especially useful. They are prepared from meat infusion or beef extract in the usual way, and titrated so that the final product is from 0.5 to 0.7 acid to phenolphthalein. In order not to interfere with the growth of sensitive bacteria and yet to indicate their number, the agar medium is made to contain only 0.5 per cent of agar, just sufficient to jell, instead of the usual 1.5 or 2 per cent. Both of these mediums are placed in test tubes so that the column of medium is at least 8 cm. tall. Pieces of fresh brain substance, equivalent to about 1 Gm., are added to the bottom of each tube to make the column approximately 10 cm. tall. The mediums are then sterilized in an autoclave at 15 pounds pressure for fifteen minutes, or in an Arnold sterilizer on three successive days. Dextrose, from a concentrated sterilized solution, is added to both mediums after sterilization to make them 0.2 per cent dextrose; also decolorized acid fuchsin. The addition of ascites fluid, blood or serum, just before use, while advantageous in special instances, is found unnecessary for routine work. The brain substance renders the bottom of the tube anaerobic; the top necessarily is aerobic, and it follows that every gradation of oxygen pressure occurs between these two points.

NARCOTIC TAX STAMP MUST BE POSTED

To the Editor:—Is it necessary that a physician post in a conspicuous place in his office the special tax stamp issued him by the Collector of Internal Revenue as evidence of his registration under the Harrison Narcotic Act? ————, M.D.

Answer.—The conspicuous posting of such stamps is required by section 3239 of the Revised Statutes which section is made applicable to the Harrison Narcotic Act by section 7 of that act.

PLUS FOUR DIACETIC ACID

To the Editor:—In The Journal, January 9, page 104, Bowcock and Wood refer to "a plus four reaction for diacetic acid." I would greatly appreciate it if you could kindly inform me how the diacetic acid test is graduated, as we would much like to introduce it into this college.

A. Stott, King George's Medical College, Lucknow, India.
Major, I. M. S.

Answer.—The inquiry was referred to Dr. H. M. Bowcock, who replied: "I would state that the method which I use in testing the urine for diacetic acid is the usual qualitative test. I use a 10 per cent water solution of ferric chloride and perform the Gerhardt test as described in the Treatment of Diabetes Mellitus, by Joslin, third edition, page 359. The reading of the test is influenced by the personal equation. I usually consider a test as four plus when the color is so deep that it will not transmit light."

COMING EXAMINATIONS

Alabama: Montgomery, July 13-16. Sec., Dr. S. W. Welch, Montgomery.

American Board of Otolaryngology, Canada: Montreal, June 1. Sec., Dr. H. W. Loeb, 1402 South Grand Boulevard, St. Louis, Mo.

Arizona: Phoenix, July 6. Sec., Dr. W. O. Sweek, 404 Heard Bldg., Phoenix.

California: San Francisco, July 12-15. Sec., Dr. Charles B. Pinkham, 906 Forum Bldg., Sacramento.

Colorado: Denver, July 6. Sec., Dr. David A. Strickler, 612 Empire Bldg., Denver.

Connecticut: Hartford, Reg. Bd., July 13-14. Sec., Dr. Robert L. Rowley, 79 Elm St., Hartford. Homeo. Bd., New Haven, July 13. Sec., Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven.

Delaware: Wilmington, Regular Board and Homeo. Board, June 15-17. Pres., Dr. H. W. Briggs, Wilmington.

Florida: St. Petersburg, June 14-15. Sec., Dr. H. M. Rowlett, Box 603, Tampa.

Georgia: Atlanta, June 9-11; Augusta, June 1-3. Sec., Dr. C. T. Nolan, Marietta, Ga.

Indiana: Indianapolis, July 13-15. Sec., Dr. Wm. T. Gott, 421 State House, Indianapolis.

Iowa: Iowa City, June 8-10. Commissioner of Health, Dr. Don M. Griswold, State Capitol, Des Moines.

Kansas: Kansas City, June 15. Sec., Dr. Albert S. Ross, Sabetha.

Kentucky: Louisville, June 24-26. Sec., Dr. A. T. McCormack, 532 West Main Street, Louisville.

Maine: Augusta, July 6-7. Sec., Dr. Adam P. Leighton, 192 State St., Portland.

Maryland: Baltimore, Reg. Bd., June 15-18. Sec., Dr. Henry M. Fitzhugh, 1211 Cathedral St., Baltimore. Homeo. Bd., June 15-16. Sec., Dr. Joseph S. Garrison, Old Orchard Rd., Ten Hills, Baltimore.

Massachusetts: Boston, July 13-15. Sec., Dr. Frank M. Vaughan, Room 144, State House, Boston.

Michigan: Ann Arbor, June 8-10. Detroit, June 14-16. Sec., Dr. Guy L. Connor, 707 Stroh Bldg., Detroit.

Minnesota: Minneapolis, June 15. Sec., Dr. A. E. Comstock, 734 Lowry Bldg., St. Paul.

Missouri: St. Louis, June 28-July 1. Chief, Licensure, Dr. Ross Hopkins, Jefferson City.

National Board of Medical Examiners: Part I, June 21-23; Part II, June 22-23. All applications should be made on or before May 15. Sec., Dr. J. S. Rodman, 1600 Walnut Street, Philadelphia.

Nebraska: Omaha, June 8-10. Director, Bur. of Exam. Bds., Mrs. Clark Perkins, Lincoln.

New Jersey: Trenton, June 15-16. Sec., Dr. Alexander MacAlister, Room 1101, Trenton Trust Bldg., Trenton.

New York: Albany, Buffalo, New York and Syracuse, June 28-July 1. Chief, Mr. Herbert J. Hamilton, Education Bldg., Albany.

North Carolina: Raleigh, June 21-25. Sec., Dr. K. P. B. Bonner, Morehead City.

North Dakota: Grand Forks, July 6. Sec., Dr. G. M. Williamson, Grand Forks.

Ohio: Columbus, June 8-11. Sec., Dr. H. M. Platter, Columbus.

Oklahoma: Oklahoma City, June 15-16. Sec., Dr. J. M. Byrum, Shawnee.

Oregon: Portland, July 6-8. Sec., Dr. U. C. Coe, 1208 Stevens Bldg., Portland.

Rhode Island: Providence, July 1-2. Sec., Dr. B. U. Richards, 315 State House, Providence.

South Carolina: Columbia, June 22. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

Texas: Austin, June 15-17. Sec., Dr. T. J. Crowe, 918 Mercantile Bank Bldg., Dallas.

Utah: Salt Lake City, July 6. Dir., Mr. J. T. Hammond, 412 State Capitol Bldg., Salt Lake City.

Vermont: Burlington, June 23. Sec., Dr. W. Scott Nay, Underhill.

Virginia: Richmond, June 16-19. Sec., Dr. J. M. Preston, 720 Shenandoah Life Bldg., Roanoke.

West Virginia: Martinsburg, July 6. Sec., Dr. W. T. Henshaw, Charleston.

Wisconsin: Milwaukee, Basic Science Board, June 12-13. Sec., Dr. M. F. Guyer, Madison. Regular Board, June 29-July 1. Sec., Dr. Robert E. Flynn, State Bank Bldg., La Crosse.

Medical Economics and Miscellany

IS UNIVERSAL LIFE INSURANCE COMING?

WILLIAM EVERETT MUSGRAVE, M.D.
San Francisco

Some 55 million individuals, or approximately one-half the people of the United States, are protected by life insurance recorded in 100 million policies of an average value of $1,333, carried (90 per cent +) by about 170 companies: there are more than three times as many insurance policies in force as there are automobiles in use. Approximately 75 billion dollars of life insurance is in force, and it is being increased at the rate of some 15 billion dollars a year. The annual income of this incomprehensible business closely approximates that of the national government, being 3 billion and some odd million dollars for each. However, in disbursements, the government wins by spending more than 3 billion, or nearly all its income, while the life insurance companies expended last year (to policyholders) about half their income.

Not only is this healthy giant of life insurance growing like the proverbial beanstalk, but it is spreading its branches like the green bay tree. It is becoming what the name life and health insurance implies, and less the death insurance of earlier days. It is branching out into the field of health and medical service to such an extent that if it is wisely guided it is likely, at no far distant date, to do medically for our citizens, by private and mutually beneficial enterprise—and do well—what Germany, England and certain other countries are unsuccessfully trying to do by government in monopolizing and socializing the practice of medicine. Our government has largely undertaken similar control of education, but so far has only fastened its tentacles into certain phases of health.

There is one phase of the commendable growth of life and health insurance, as private business, that concerns all people and ought to be better understood than it is. It consists essentially in a weakening of the health requirements for policy purchasers and extension of the medical care of policyholders, apparently under the philosophy that the lowered health standards for purchasers will materially increase the *volume of business,* and that this, together with more extensive medical supervision of defective policyholders' health, will take care of the extra hazards inherent in this new development of business. It may be that this is a fact. In any event, we may rest assured that the financiers who determine the policies of insurance carriers are not wholly altruistic in their actions and that they are doing as little guessing as possible in taking this definite step. To be sure, not all companies admit that the doing away with medical examinations of applicants for insurance will result in increasing life hazards among their assured, and none of them call particular attention to it as a probability.

One speaker at the annual meeting of the Association of Life Insurance Presidents (Dec. 3, 1925) made the argument and quoted statistics which he interpreted to show that losses are greater among risks based on medical examination than among those selected without such examination. Other speakers at this conference considered that the probable increased losses among nonmedically examined risks would be more than offset by the saving of the $15,000,000 paid to physicians annually. Only one or two of the speakers at this great association of insurance policy makers called particular attention to the savings, as well as the increased benefits to policyholders, clearly indicated by their extending health supervision and the practice of medicine among their assured, now gaining such headway among the companies.

The selling of insurance without medical selection of risks and without health supervision of the insured is as old as life and health insurance. The business started that way in England some 200 odd years ago. Later, medical examination of risks was made a requisite for policy purchasers, and for many years was almost universally followed. There a certain amount of medical supervision of the insured was introduced, at first frankly as a protection to the financial investment: about as altruistic as the old encouragement of prolific human breeding because profligate rulers needed more "war fodder." With the expansion of medical care, and consequent *prolonging of the lives of policyholders,* some companies began to lower their standards of medical scrutiny of insurance purchasers. The last few years has seen such an astonishing decrease in the medical requirements for applicants for insurance and such a tremendous increase in the volume and variety of medical care supplied to those insured that, in effect, it makes of life insurance a new type of business with vast potentialities for good and evil.

If vital and actuarial statistics that have been accumulating over the years are even approximately correct, there ought to be available sufficient data about all life hazards on which to base a safe premium rate for the insurance of persons of all ages and most conditions of health; this assuming, of course, adequate volume of business and sufficient fluid reserves to meet possible extraordinary situations produced by epidemics and catastrophes. Obviously, the premiums on policies covering miscellaneous risks must be higher than is necessary for risks selected by thorough medical examination, and carriers dealing in the more hazardous form of business would call for scrupulous financial safeguards.

That some leaders in the insurance field recognize and appreciate the vast difference between life and health risks selected in a distant central office, from medical data secured by nonmedical people, plus the examination of a specimen of urine, also sent by mail, and risks that are based on the additional findings of a competent physician, is apparent in their public statements. The arguments and "not conclusive" statistics quoted by some insurance authorities to support their conclusions, that medical examinations have little or no value in the selection of risks, loses weight by the fact that they, as well as other companies, strengthen and enlarge their medical service to their assured as they lower their standards of acceptance. Medical service is, of course, precisely as valuable, or valueless, in the one instance as in the other.

However, that more and more of the reliable insurance companies are rapidly expanding and promoting insurance, without the customary careful selection of risks based on medical examination, indicates that they have sufficient facts to warrant promotion and extension of a practice headed toward universal or unrestricted life insurance. Considered solely in the interests of public health and welfare—which is the only way physicians or any one else should consider it—there is much to commend this venture. It is a logical and important step toward that even more desirable goal when accident and health insurance carriers will also liberalize their policies until they too will write policies with so few limitations, exemptions and restrictions that most people can secure—voluntarily—coverage that ameliorates the dangerous and worrisome hazards of health and distributes the costs and *personal losses incident to accidents and infirmities.* In the meantime it is to be hoped that leaders in the gigantic business of life insurance will so develop their plans that more and more citizens may purchase, at costs as reasonable as consistent with the hazards of the business, that comfort which all people have come to recognize as a normal blessing of life insurance.

HEALTH SERVICE FOR POLICYHOLDERS

Supervision of the health of policyholders, which is being expanded to offset the increased hazards inherent in lowering the standards for acceptable risks, is a movement of transcendent importance to all people and particularly to physicians and other health-conserving agencies. Several life insurance companies and many accident and health insurers have been feeling their way for a long time toward the goal at which their financial interests would be better protected, the comfort and lives of their insured extended, and society served by the development of their own medical departments to serve the health of their policyholders. President Haley Fiske of the Metropolitan asked the Association of Life Insurance Presidents recently, "Is there any ill or contingency in life our business will not cover?" In answering the question, he said, "The specters before wage and salaried men and women are death, sickness and accident, unemployment and dependent old age. It is the true function of life insurance to banish these specters." The Metropolitan's plans for banishing these specters is summed up in this quotation from his address:

> "The extraordinary number of policyholders, probably not far from half the population, and in Eastern cities a much larger proportion, put upon the company and its officers a responsibility as to public health and welfare. We see the companies attacking disease, offering diagnosis and advice to individuals, supplying them with health literature, cooperating with government and health and school officials, reaching out to give education to the people and even to the children, in preventive medicine. The companies' official staff must now comprise not only insurance men but financial experts, social students, physicians, specialists in health, in welfare, in education, in publicity. It is not for advertising that one company nurses free of change its sick poor by two and a half million yearly visits, distributes literature on prevention and cure of sickness from practically every known disease to the extent of forty millions of pamphlets a year, broadcasts health talks, teaches physical culture by radio; publishes, in seventeen millions of copies of periodicals, its monthly talks on health, with no reference to insurance. It is the fulfilment of responsibility to one sixth of the population covered by its policies. It is concern for public health."

As yet there is no uniformity in the quality, quantity and character of the services supplied by the various companies "free" to the assured but, of course, paid for in premiums. While some carriers are rendering this service themselves, more of them are "farming" it out and presumably thereby not only covering the ostrich's head but making the bird entirely invisible; and some have not yet undertaken this form of medical practice. There are appealing talking points in favor of these great corporations' adding the practice of medicine—usually disguised in name at least—to their other business ventures; but it remains to be demonstrated that they realize the intelligence or the size of the bear whose tail they are grasping. However, it is easier to respect the company that tackles its own bear than it is those who exercise the caution of employing self-styled middlemen to handle their hot chestnuts.

Any practical movement that will insure better health by improved medical care and thus prolong life and promote happiness, regardless of its possible effects on physicians and other existing health agencies, ought to be encouraged. But before steps are taken calculated to change radically the ages-old custom which recognizes health as a personal matter, served by personally selected advisers, to a more public matter to be attended to by the agents of some corporation, all the logical consequences ought to be reviewed.

STATE MEDICINE MOVEMENTS

The road of social progress is strewn with the wrecks of schemes having for their ostensible purpose the commendable one of promoting health and longevity by the introduction of some wholesale organized system of medical care. One of the largest and oldest of these movements has for its purpose the control of health by the state, to be supported by taxes and served by government employees "free" alike to all citizens. In several countries this scheme has developed into a government monopoly, compulsory for the majority of the citizens. These "compulsory health insurance" or "state medicine" movements, as they are called, vary considerably in methods, but in all the objective is the laudable one of promoting health, treating the sick and prolonging life. They all propose to do this by substituting, for the traditional personal health care by health advisers selected by the patient, wholesale practice carried on by government departments.

Throughout the fifty or more years these experts have been active, they have been under such constant attack by the sick as well as those who serve the sick that, even with all the power of the government, vast numbers of people have continued to appeal to private health agencies for personal service, leaving to the government largely only clients who for one reason or another could not help themselves, and leaving for the government service largely such physicians and other health agencies as prefer a poorly paid government job to the uncertainties of personal practice.

Direct and open efforts to governmentalize health and medical service have always been defeated in the United States, but the leaders of this brand of socialism and commercialism have succeeded in projecting their tentacles far into the social structure in a score or more directions by governmentalizing health service for this and that group of citizens. The most promising antidote in sight to the progressing movement calculated to governmentalize, socialize, sovietize health is the rising tide of associations, societies, groups and corporations that propose to distribute the costs and character of health service on some basis of voluntary agreement between the beneficiary, the health-serving agency and the responsible organization. There are history-making possibilities inherent in this situation, but that they are being intelligently grasped remains to be seen. The idea needs leadership of a kind that will protect the interests of the beneficiary, the health agencies who serve and the investors, and which will do these things in a manner calculated to create and sustain public approval. The great insurance companies are in a position to do this more than ever now that the life companies are enlarging their field to include much of what was formerly considered to be health and accident insurance and personal health service by personally selected physicians. It is quite true that the life companies do not emphasize the fact that they are also health insurers; but when they lower their standards of admission and plan to take care of the consequently increased hazards by an extended and improved medical service to their policyholders, they thereby enter the broader and, to society, the far more useful service of health insurance. Although insurance companies could be charged with conducting this improved medical service for the purpose of prolonging the date when death payments may be due, nevertheless, theoretically at least, it pays the policyholder dividends in better health and longevity, more comforting to him and society than are death benefits.

The future consequences of this expanded and expanding type of life, health and accident insurance on existing agencies of health is problematic; but if the future practice of medicine and health service is to be by employees of insurance corporations, as the only alternative to bureaucratic government service, the interests of society, as well as those who serve, lies with private business. If, as claimed by its leaders, a "true function of life insurance is to banish the specters of sickness and accident," we are destined to see a battle royal between government, managed by politics, and the largest of all private businesses, managed by wealth, over the most precious of human assets. In the meantime, those who serve and those served may only look on, and some of them—pray.

Medical Economics and Miscellany

IS UNIVERSAL LIFE INSURANCE COMING?

WILLIAM EVERETT MUSGRAVE, M.D.
San Francisco

Some 55 million individuals, or approximately one-half the people of the United States, are protected by life insurance recorded in 100 million policies of an average value of $1,333, carried (90 per cent +) by about 170 companies: there are more than three times as many insurance policies in force as there are automobiles in use. Approximately 75 billion dollars of life insurance is in force, and it is being increased at the rate of some 15 billion dollars a year. The annual income of this incomprehensible business closely approximates that of the national government, being 3 billion and some odd million dollars for each. However, in disbursements, the government wins by spending more than 3 billion, or nearly all its income, while the life insurance companies expended last year (to policyholders) about half their income.

Not only is this healthy giant of life insurance growing like the proverbial beanstalk, but it is spreading its branches like the green bay tree. It is becoming what the name life and health insurance implies, and less the death insurance of earlier days. It is branching out into the field of health and medical service to such an extent that if it is wisely guided it is likely, at no far distant date, to do medically for our citizens, by private and mutually beneficial enterprise—and do well—what Germany, England and certain other countries are unsuccessfully trying to do by government in monopolizing and socializing the practice of medicine. Our government has largely undertaken similar control of education, but so far has only fastened its tentacles into certain phases of health.

There is one phase of the commendable growth of life and health insurance, as private business, that concerns all people and ought to be better understood than it is. It consists essentially in a weakening of the health requirements for policy purchasers and extension of the medical care of policyholders, apparently under the philosophy that the lowered health standards for purchasers will materially increase the volume of business, and that this, together with more extensive medical supervision of defective policyholders' health, will take care of the extra hazards inherent in this new development of business. It may be that this is a fact. In any event, we may rest assured that the financiers who determine the policies of insurance carriers are not wholly altruistic in their actions and that they are doing as little guessing as possible in taking this definite step. To be sure, not all companies admit that the doing away with medical examinations of applicants for insurance will result in increasing life hazards among their assured, and none of them call particular attention to it as a probability.

One speaker at the annual meeting of the Association of Life Insurance Presidents (Dec. 3, 1925) made the argument and quoted statistics which he interpreted to show that losses are greater among risks based on medical examination than among those selected without such examination. Other speakers at this conference considered that the probable increased losses among nonmedically examined risks would be more than offset by the saving of the $15,000,000 paid to physicians annually. Only one or two of the speakers at this great association of insurance policy makers called particular attention to the savings, as well as the increased benefits to policyholders, clearly indicated by their extending health supervision and the practice of medicine among their assured, now gaining such headway among the companies.

The selling of insurance without medical selection of risks and without health supervision of the insured is as old as life and health insurance. The business started that way in England some 200 odd years ago. Later, medical examination of risks was made a requisite for policy purchasers, and for many years was almost universally followed. There a certain amount of medical supervision of the insured was introduced, at first frankly as a protection to the financial investment: about as altruistic as the old encouragement of prolific human breeding because profligate rulers needed more "war fodder." With the expansion of medical care, and consequent prolonging of the lives of policyholders, some companies began to lower their standards of medical scrutiny of insurance purchasers. The last few years has seen such an astonishing decrease in the medical requirements for applicants for insurance and such a tremendous increase in the volume and variety of medical care supplied to those insured that, in effect, it makes of life insurance a new type of business with vast potentialities for good and evil.

If vital and actuarial statistics that have been accumulating over the years are even approximately correct, there ought to be available sufficient data about all life hazards on which to base a safe premium rate for the insurance of persons of all ages and most conditions of health; this assuming, of course, adequate volume of business and sufficient fluid reserves to meet possible extraordinary situations produced by epidemics and catastrophes. Obviously, the premiums on policies covering miscellaneous risks must be higher than is necessary for risks selected by thorough medical examination, and carriers dealing in the more hazardous form of business would call for scrupulous financial safeguards.

That some leaders in the insurance field recognize and appreciate the vast difference between life and health risks selected in a distant central office, from medical data secured by nonmedical people, plus the examination of a specimen of urine, also sent by mail, and risks that are based on the additional findings of a competent physician, is apparent in their public statements. The arguments and "not conclusive" statistics quoted by some insurance authorities to support their conclusions, that medical examinations have little or no value in the selection of risks, loses weight by the fact that they, as well as other companies, strengthen and enlarge their medical service to their assured as they lower their standards of acceptance. Medical service is, of course, precisely as valuable, or valueless, in the one instance as in the other.

However, that more and more of the reliable insurance companies are rapidly expanding and promoting insurance, without the customary careful selection of risks based on medical examination, indicates that they have sufficient facts to warrant promotion and extension of a practice headed toward universal or unrestricted life insurance. Considered solely in the interests of public health and welfare—which is the only way physicians or any one else should consider it—there is much to commend this venture. It is a logical and important step toward that even more desirable goal when accident and health insurance carriers will also liberalize their policies until they too will write policies with so few limitations, exemptions and restrictions that most people can secure—voluntarily—coverage that ameliorates the dangerous and worrisome hazards of health and distributes the costs and personal losses incident to accidents and infirmities. In the meantime it is to be hoped that leaders in the gigantic business of life insurance will so develop their plans that more and more citizens may purchase, at costs as reasonable as consistent with the hazards of the business, that comfort which all people have come to recognize as a normal blessing of life insurance.

HEALTH SERVICE FOR POLICYHOLDERS

Supervision of the health of policyholders, which is being expanded to offset the increased hazards inherent in lowering the standards for acceptable risks, is a movement of transcendent importance to all people and particularly to physicians and other health-conserving agencies. Several life insurance companies and many accident and health insurers have been feeling their way for a long time toward the goal at which their financial interests would be better protected, the comfort and lives of their insured extended, and society served by the development of their own medical departments to serve the health of their policyholders. President Haley Fiske of the Metropolitan asked the Association of Life Insurance Presidents recently, "Is there any ill or contingency in life our business will not cover?" In answering the question, he said, "The specters before wage and salaried men and women are death, sickness and accident, unemployment and dependent old age. It is the true function of life insurance to banish these specters." The Metropolitan's plans for banishing these specters is summed up in this quotation from his address:

> "The extraordinary number of policyholders, probably not far from half the population, and in Eastern cities a much larger proportion, put upon the company and its officers a responsibility as to public health and welfare. We see the companies attacking disease, offering diagnosis and advice to individuals, supplying them with health literature, cooperating with government and health and school officials, reaching out to give education to the people and even to the children, in preventive medicine. The companies' official staff must now comprise not only insurance men but financial experts, social students, physicians, specialists in health, in welfare, in education, in publicity. It is not for advertising that one company nurses free of change its sick poor by two and a half million yearly visits, distributes literature on prevention and cure of sickness from practically every known disease to the extent of forty millions of pamphlets a year, broadcasts health talks, teaches physical culture by radio; publishes, in seventeen millions of copies of periodicals, its monthly talks on health, with no reference to insurance. It is the fulfilment of responsibility to one sixth of the population covered by its policies. It is concern for public health."

As yet there is no uniformity in the quality, quantity and character of the services supplied by the various companies "free" to the assured but, of course, paid for in premiums. While some carriers are rendering this service themselves, more of them are "farming" it out and presumably thereby not only covering the ostrich's head but making the bird entirely invisible; and some have not yet undertaken this form of medical practice. There are appealing talking points in favor of these great corporations' adding the practice of medicine—usually disguised in name at least—to their other business ventures; but it remains to be demonstrated that they realize the intelligence or the size of the bear whose tail they are grasping. However, it is easier to respect the company that tackles its own bear than it is those who exercise the caution of employing self-styled middlemen to handle their hot chestnuts.

Any practical movement that will insure better health by improved medical care and thus prolong life and promote happiness, regardless of its possible effects on physicians and other existing health agencies, ought to be encouraged. But before steps are taken calculated to change radically the ages-old custom which recognizes health as a personal matter, served by personally selected advisers, to a more public matter to be attended to by the agents of some corporation, all the logical consequences ought to be reviewed.

STATE MEDICINE MOVEMENTS

The road of social progress is strewn with the wrecks of schemes having for their ostensible purpose the commendable one of promoting health and longevity by the introduction of some wholesale organized system of medical care. One of the largest and oldest of these movements has for its purpose the control of health by the state, to be supported by taxes and served by government employees "free" alike to all citizens. In several countries this scheme has developed into a government monopoly, compulsory for the majority of the citizens. These "compulsory health insurance" or "state medicine" movements, as they are called, vary considerably in methods, but in all the objective is the laudable one of promoting health, treating the sick and prolonging life. They all propose to do this by substituting, for the traditional personal health care by health advisers selected by the patient, wholesale practice carried on by government departments.

Throughout the fifty or more years these experts have been active, they have been under such constant attack by the sick as well as those who serve the sick that, even with all the power of the government, vast numbers of people have continued to appeal to private health agencies for personal service, leaving to the government largely only clients who for one reason or another could not help themselves, and leaving for the government service largely such physicians and other health agencies as prefer a poorly paid government job to the uncertainties of personal practice.

Direct and open efforts to governmentalize health and medical service have always been defeated in the United States, but the leaders of this brand of socialism and commercialism have succeeded in projecting their tentacles far into the social structure in a score or more directions by governmentalizing health service for this and that group of citizens. The most promising antidote in sight to the progressing movement calculated to governmentalize, socialize, sovietize health is the rising tide of associations, societies, groups and corporations that propose to distribute the costs and character of health service on some basis of voluntary agreement between the beneficiary, the health-serving agency and the responsible organization. There are history-making possibilities inherent in this situation, but that they are being intelligently grasped remains to be seen. The idea needs leadership of a kind that will protect the interests of the beneficiary, the health agencies who serve and the investors, and which will do these things in a manner calculated to create and sustain public approval. The great insurance companies are in a position to do this more than ever now that the life companies are enlarging their field to include much of what was formerly considered to be health and accident insurance and personal health service by personally selected physicians. It is quite true that the life companies do not emphasize the fact that they are also health insurers; but when they lower their standards of admission and plan to take care of the consequently increased hazards by an extended and improved medical service to their policyholders, they thereby enter the broader and, to society, the far more useful service of health insurance. Although insurance companies could be charged with conducting this improved medical service for the purpose of prolonging the date when death payments may be due, nevertheless, theoretically at least, it pays the policyholder dividends in better health and longevity, more comforting to him and society than are death benefits.

The future consequences of this expanded and expanding type of life, health and accident insurance on existing agencies of health is problematic; but if the future practice of medicine and health service is to be by employees of insurance corporations, as the only alternative to bureaucratic government service, the interests of society, as well as those who serve, lies with private business. If, as claimed by its leaders, a "true function of life insurance is to banish the specters of sickness and accident," we are destined to see a battle royal between government, managed by politics, and the largest of all private businesses, managed by wealth, over the most precious of human assets. In the meantime, those who serve and those served may only look on, and some of them—pray.

805 Balboa Building.

REPORT ON NATIONAL HEALTH INSURANCE

Important recommendations involving substantial changes in scope and administration are contained in the report of a royal commission appointed in England in 1924 to inquire into the scheme of national health insurance established by the acts of 1911-1912, and to report what, if any, alterations, extensions or developments should be made in regard to the scope of that scheme and the administrative, financial and medical arrangements set up under it. The scheme came into operation in July, 1912, and a series of amending acts followed, from 1913 to the consolidating act of 1924. The original act had a complexity which in practice yielded no adequate compensating advantage, and this led to amendments aiming at simplification and modification of administration. A second main cause leading to amendment was the war and its economic consequences, but it is a striking tribute to the lines on which the original act was constructed that its administration was able to bear the strain imposed by war conditions so early in its history. The present inquiry is the first general and comprehensive investigation of a scheme under which more than 15,000,000 persons are insured. The commission received little evidence directed against the scheme as a whole, although public invitation was given to any bodies or persons who desired to make representations. There does not now appear to be any considerable body of opinion adverse to the principle of national health insurance. Indeed, a large volume of evidence in its favor was received from many different quarters, testifying to the advantages in health and social security derived under it. The report presents no fewer than 122 recommendations. The first states that national health insurance has established itself as a permanent feature of the social system in this country, and should be continued on its present compulsory and contributory basis, subject to the changes proposed in the report. It is suggested that to the persons at present required to be insured as employed contributors there should be added "persons engaged in employment under a contract for the performance of manual labor for the purpose of any trade or business except so far as such employment may be excluded by a special order." It is also suggested that the revenue of the scheme should continue to be derived from insured persons, employers, with a payment from the national exchequer of a proportionate part of the cost of the benefits and of their administration; and that the cost of the central administration of the scheme should continue to be a charge on the exchequer.

MEDICAL BENEFIT

Medical benefit is declared to have been a valued and successful element in the scheme. Heretofore medical benefit was confined to a general practitioner service; but this limitation detracted from the value of the benefit, and its removal is declared to be urgently desirable. In view of the financial burden of the various social services at present, it is proposed that no extensions of benefit involving substantial additional expenditure should be contemplated now or in the immediate future, but that any immediate changes in the scheme should be limited to those possible within its present financial resources. An analysis of the expenditure of approved societies on sickness and disablement benefits reveals the need for more effective supervision of claims for those benefits.

PROPOSED BENEFIT EXTENSIONS

The extensions of benefits to be made are placed in the following order of priority: (*a*) extension of the scope of medical benefit; (*b*) the provision of allowances in respect of dependents of insured persons in receipt of sickness or disablement benefit; (*c*) improved provision at the time of pregnancy and childbirth for insured women and the wives of insured men; (*d*) provision of dental treatment. The extension of the scope of medical benefit should take the form of the provision of: (*a*) expert medical advice and treatment for persons who can travel to meet the specialist; (*b*) expert advice for persons who are unable to travel; (*c*) laboratory services. Inpatient treatment in hospitals, major operations in the home, maternity services and dental service should not be included at present.

SPECIALIST TREATMENT

The extended service should be provided, not by way of development of the outpatient work of the hospitals, but through an independent scheme organized, under the general direction of the ministry, throughout the whole country by the insurance committees. Provision should be made for the closest cooperation between the general practitioners and the specialists. Any practitioner possessing the requisite qualifications should be entitled to take part in the work, and the decision as to whether particular practitioners possess these qualifications should lie in the hands of a mixed lay and medical committee for each area. In the initial stages of the scheme, arrangements might be made for patients who are able to travel to attend at the specialist's office, at the outpatient departments of hospitals, or at clinics established by the local administrative authority, as may be found most convenient.

SOME OBJECTIONS

Two of the members of the commission, while concurring in the terms of the majority report, consider that there are two further matters which ought not to be ignored, particularly if due weight is to be given to the reactions of our social legislation on the trade and industry of the country. They postulate, as an elementary principle, that in promoting schemes of social legislation the state should avoid incurring any expenditure not essential to the end in view, and that the funds required should be so collected as to involve a minimum disturbance to industrial enterprise. The lack of coordination in our social services is the first point to which they draw attention, and they point out the inconvenience and, by implication, the waste which it occasions. While they do not dissent from the present arrangements, under which the employer's contribution is on a flat rate proportioned to the number of employees, they doubt whether the reactions of the cost of health insurance on the trade and industry of the country are fully appreciated. At present the contribution made by employers to the health insurance fund is roughly proportioned to the wages bill, but the wages bill has no necessary relation to the profits of a firm. In consequence, a firm employing a large staff will contribute largely to the health insurance fund, even though it be in a depressed trade and may not at the time be covering even overhead expenses; on the other hand, provided it employs few men, a prosperous firm will contribute but little. It follows that the ultimate incidence of the tax and its reaction on trade may vary greatly from one industry to another. In certain cases it may doubtless be possible in large measure to pass the burden on to the consumer; elsewhere this may be wholly impossible. The burden imposed by social insurance on industry is in certain cases very real, and, unfortunately, it is at present most onerous where there is least capacity to bear it, in those industries, as it happens, which are most essential to the country's prosperity. In the case of the "sheltered occupations" (those which are not exposed to competition) little inconvenience may arise; the burden may be borne or passed on. But in the case of the unsheltered industries, in which the full rigor of foreign competition has already produced a position of grave embarrassment reflected in the unemployment returns, it is not permissible to regard the burden of social insurance as negligible and free from possible detrimental reactions on the prosperity of the country and, indeed, on the employment of the worker.

Book Notices

Comparative Physiology. By Lancelot T. Hogben, M.A., D.Sc., Assistant Professor in Zoology, McGill University. Cloth. Price, $3. Pp. 219, with 44 illustrations. New York: The Macmillan Company, 1926.

This is a well written, critical and interesting volume on comparative physiology, with chapters on muscular contraction, ciliary activity, secretion, respiration, nutrition, circulation, endocrine coordination, nervous coordination, animal behavior, fertilization, inheritance and development, particularly as illustrated in the lower animals. The book is addressed to two classes of students—advanced students of zoology who need information and orientation on the functional side of biology, and advanced medical students who may be or should be interested in the general manifestations of life and disease as it appears in the entire animal kingdom. The author notes, quite correctly, that there exists today no up-to-date book on comparative physiology in the English language. The present volume aims to supply this need. The modesty of the claims of the author for erudition and judgment in the presentation is as noteworthy as is the excellence of the book. The volume can be recommended for interesting study and information to any physician who still retains or who may long to reestablish his contact and information in general animal life. Even recent graduates in medicine can read the volume with profit, because even in the best medical schools most of the data in general physiology are left out of the courses in physiology because of lack of time.

Die Geschlechtskrankheiten. Leitfaden für Studierende und Aerzte. Von H. Löhe, A. o. Prof. A.D. Univ. Berlin. Paper. Price, 8.40 marks. Pp. 213, with 75 illustrations. Berlin: S. Karger, 1926.

This is a collection of the postgraduate lectures that the author used to give at the Berlin dermatologic clinic. They cover the clinical pathology, diagnosis and treatment of gonorrhea and syphilis. While written along the customary lines, they excel in precise and clear presentation and in the inductive method applied to the discussion of the therapeutic measures. The illustrations are instructive. A special chapter is devoted to venereal prophylaxis. There is a tabulation of prescriptions that should prove useful.

Statistical Analysis. By Edmund E. Day, Professor of Economics, School of Business Administration, University of Michigan. Cloth. Price, $4. Pp. 459, with illustrations. New York: The Macmillan Company, 1925.

This is primarily designed as a general introduction to statistical methods. It is clearly written and well provided with illustrations. The examples and illustrations are based chiefly on economic data, so that the book is not especially adapted for physicians or other students of vital statistics. The author's handling is conservative and never extreme. He sees clearly that the statistical method can never take the place of experiment where experiment is possible. Applied to data such as are found in many biologic problems where many separate and distinct factors are concerned and where experiment is not feasible, the statistical method may be valuable. The temper of the discussion may be gathered from the following statement, which might profitably be kept in mind by all who attempt to use the statistical method of analysis: "Statistical results may create presumptions in favor of certain conclusions. They rarely dispose of matters completely."

Respiratory Function in Disease. By Jonathan C. Meakins, M.D., C.M., F.R.C.P., Professor of Medicine, McGill University, and H. Whitridge Davies, M.B., B.S., Lecturer in Methods of Clinical Investigation in the Department of Therapeutics, University of Edinburgh. Cloth. Price, 28 shillings net. Pp. 478, with 63 illustrations. London: Oliver and Boyd, 1925.

This book, intended mainly for those engaged in the practice and teaching of medicine, presents the subject of disturbed respiratory function from the standpoint of clinical medicine. In it are collected the results of important investigative work scattered throughout the enormous literature that has appeared on this subject during the last few years. The authors attempt to give to physicians a working knowledge of the chemical and physiologic facts concerning respiration. Part I is concerned with normal respiratory function. The theories and known facts of hemorespiratory exchange are considered. Part II deals with respiratory function under abnormal conditions. Chapters are devoted to vital capacity and lung volume; respiratory exchange and the basal metabolic rate; therapeutics of respiratory disturbances; and methods of investigation. An extensive bibliography is appended. The work serves its purpose in presenting in simple terms the fundamental facts of a technical subject.

A Text-Book of Psychology for Nurses. By Maude B. Muse, R.N., A.M., Instructor of Nursing Education at Teachers College, Columbia University. Cloth. Price, $2.50 net. Pp. 351, with illustrations. Philadelphia: W. B. Saunders Company, 1925.

The need of some knowledge of the patient as a human being instead of as a mere collection of organs each of which is subject to disease is steadily becoming recognized as essential for all who would undertake the care and treatment of the sick. To no group is this of greater importance than to the nurse, not only as regards the care of her patients but also in relation to her own satisfactory adjustment to her work. In this volume is presented an outline of the modern conception of human behavior expressly designed by a nurse for the use of nurses. With this in view, the various topics are throughout illustrated by situations taken from the hospital and training school. It is written in simple language and is probably as brief as is consistent with a practical working knowledge. It can be safely recommended for use in training schools for nurses.

Visual Field Studies. By Ralph I. Lloyd, M.D., F.A.C.S., Surgeon, N. Y. Ophthalmic Hospital. Cloth. Price, $6 net. Pp. 216, with 124 illustrations. New York: Technical Press, 1926.

This is the outgrowth of a series of postgraduate lectures, elaborated into a permanent form. It starts with a brief, but interesting history of perimetry as developed during the latter half of the last century, and progresses into the modern concepts of both central and peripheral perimetry. The chapter devoted to retinal physiology is written in a refreshing manner in that the practical application of the dry-as-dust laws is stressed. It may be remembered that the author developed the present day stereocampimeter and consequently is a red-hot enthusiast for binocular fixation in perimetry as well as an ardent devotee of tangential perimetry. According to the trend of modern thought, he seems to be justified. The method of taking visual fields, central and peripheral, arciform and tangential, is given at length, and the ensuing results are analyzed clearly and forcefully. Fully fifty pages are devoted to the visual fields in retrobulbar disease, and the differences due to varied etiologic factors elaborated on. Extensive studies of the so-called amblyopia ex anopsia are included, and the author inclines toward the opinion that this condition results from retinal birth hemorrhages. The book is well worth while, not for students, but for ophthalmologists, beginners as well as others. A rather unique feature is a diagram on the front cover representing an early perimetric experimental apparatus used by Aubert and Foster in 1857.

Methodik der Untersuchungen von Nervenelementen des makro- und makro-mikroskopischen Gebietes. Teil I. Von Prof. Dr. W. Worobiew. Paper. Pp. 130, with 39 illustrations. Berlin: Oscar Rothacker.

Gross anatomic research as ordinarily carried out through dissection with the naked eye and natural light, has certain limitations. For instance, it is not possible, under such conditions, to follow up the course of afferent nerves in the heart muscles, the walls of the stomach, or the bladder. The study of finer ramifications of the nerve fibers, their connections with the ganglion cells and other structures is left to the histologist. The latter, however, is able to study only small areas and has to resort to reconstruction methods in order to bring out the topography of the finer nerve structures. Areas that are inaccessible to the gross anatomist and do not actually belong to the domain of the histologist are named by Worobiew macro-microscopic. In this book, which is merely an introduction, he describes the methods used in "macromicroscopic" studies by himself and his pupils secting is done with very fine instruments, under a binocular dissecting microscope, the parts being placed in suitable clearing mediums and stained in toto; that is, the entire object (uterus, heart, stomach) is stained and dissected. A number of beautiful photographs show the remarkable results obtained by the macromicroscopic methods described. They clearly show, for instance, the ganglionic plexuses in the walls of the heart and the bladder, the nerves of the tendons, and the ganglion cells in the stomach walls. In short, the topography of final nerve ramifications and their relationship to the ganglionic system is brought out with remarkable clearness. It is unquestionably a highly scientific and useful book, well written and excellently edited.

Books Received

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for more extensive review in the interests of our readers and as space permits.

Chemistry in Agriculture: A Cooperative Work Intended to Give Examples of the Contribution Made to Agriculture by Chemistry. Edited by Joseph S. Chamberlain, Professor of Agricultural and Organic Chemistry, Massachusetts Agricultural College. Advisory Editor, C. A. Browne, Chief, Bureau of Chemistry, United States Department of Agriculture. Cloth. Price, $1. Pp. 384, with illustrations. New York: The Chemical Foundation, Inc., 1926.

Glorification of modern chemical advance by experts in various fields.

Puerperal Septicæmia: Its Causation, Symptoms, Prevention and Treatment. Being the Substance of a Thesis Submitted to the Royal Society of Medicine in June, 1924, and Awarded the Nicholls Prize. By George Geddes, M.D., C.M. Cloth. Price, $4. Pp. 200, with illustrations. New York: William Wood & Co., 1925.

Prize thesis reaching conclusion that only delivery by trained midwife in hospitals under medical supervision will lower still further deaths from puerperal sepsis.

Stauungstypen bei Kreislaufstörungen. Mit besonderer Berücksichtigung der exsudativen Perikarditis. Eine anatomische, experimentelle und klinische Untersuchung. Von Herbert Elias, Assistent an der I. med. Klinik, und Adolf Feller, Assistent am path.-anat. Institute. Paper. Price, 24 marks. Pp. 232, with 93 illustrations. Berlin: Julius Springer, 1926.

Research on exudative pericarditis and heart disease in general.

Nervous and Mental Disorders from Birth Through Adolescence. By B. Sachs, M.D., Consulting Neurologist to the Mount Sinai and Montefiore Hospitals, and Louis Hausman, M.D., Instructor in Neuro-Anatomy, Cornell University Medical College. Cloth. Price, $10 net. Pp. 861, with 110 illustrations. New York: Paul B. Hoeber, Inc., 1926.

Consideration from neurologic point of view of nerve disturbances with highly conservative discussion of psychologic and psychiatric problems.

The Diagnosis, Treatment and End Results of Tuberculous Disease of the Hip Joint. By George Perkins, M.Ch., F.R.C.S., Assistant Surgeon to the Royal National Orthopædic Hospital. Cloth. Price, $1.75. Pp. 118, with 32 illustrations. New York: Oxford University Press, 1926.

Monographic essay, emphasizing recumbency, traction and fixation, combined with open air, hygiene and heliotherapy for treatment.

Advising the Tuberculous About Employment. By W. I. Hamilton, Personnel Director, Boomer-Dupont Properties Corporation, New York, and T. B. Kidner, Institutional Consultant, Technical Adviser, Central New England Sanatorium Association Industrial Settlement. Cloth. Price, $2. Pp. 171. Baltimore: Williams & Wilkins Company, 1926.

Suggestions on the adjustment of the handicapped to their occupational environment.

The Private Practitioner as Pioneer in Preventive Medicine: Being the annual oration of the Hunterian Society, 1926. By Sir George Newman, K.C.B., M.D., D.C.L. Paper. Price, 30 cents. Pp. 47, with 1 illustration. New York: Oxford University Press, 1926.

Emphasizing life of John Hunter and showing how general practitioner has helped to build our knowledge of preventive medicine.

The Bacteriophage and Its Behavior. By F. D'Herelle, M.D., Director of Laboratories at Alexandria, Egypt. Translated by George H. Smith, Ph.D., Associate Professor of Bacteriology and Immunology, School of Medicine, Yale University. Cloth. Price, $5. Pp. 629, with illustrations. Baltimore: Williams & Wilkins Company, 1926.

The last word, concluding with a chapter on phagotherapy for dysentery and staphylococcus infections in which the author deprecates premature commercial exploitation.

Young's Practice of Urology. Based on a Study of 12,500 Cases. By Hugh H. Young and David M. Davis. With the Collaboration of Franklin P. Johnson. Volumes I and II. Cloth. Price, per set, $25 net. Pp. 1484, with 1003 illustrations. Philadelphia: W. B. Saunders Company, 1926.

A monumental text based on vast personal experience and research, beautifully illustrated.

An Introduction to the Study of X-Rays and Radium. By Hector A. Colwell, M.B., D.P.H., Director of the Radiological Department, King's College Hospital, and Cecil P. G. Wakeley, F.R.C.S., F.R.S., Assistant Surgeon, King's College Hospital. Cloth. Price, $3.35. Pp 203, with 37 illustrations. New York: Oxford University Press, 1926.

Handbook of elementary instruction on nature and application of radioactive substances.

The Endocrine Organs: An Introduction to the Study of Internal Secretion. Part II. The Pituitary; The Pineal; The Alimentary Canal; The Pancreas, and the Sex Glands. By Sir E. Evidence of Injuries to Others—Use of Medical Works

(E. I. du Pont de Nemours & Co. v. White (U. S.), 8 Fed. R. (2d) 5)

The United States Circuit Court of Appeals, third circuit, holds that in this action, in which plaintiff White sued the defendant for alleged failure to take reasonable care to prevent the escape of noxious and poisonous gases in its factory where he worked, it was not error to admit the testimony of three other employees, who worked in the same rooms where he did, that the gases in those rooms produced practically the same effect on them as on him. In evidencing the quality of gas, such as phosgene and chlorine (to which the plaintiff alleged that he was subjected by the negligence of the defendant), by instances of its effects on others who worked in and inhaled it, the natural and logical limitation was that the evidential instances should have occurred under substantially the same circumstances; otherwise the ill effects might be attributed to the influence of some other element introduced by the differing circumstances. While in the use of this mode of proof unfair surprise and confusion of issues inevitably arise and often serve to exclude the evidence, yet the almost universal attitude of courts at the present time is to admit such evidence, subject to the limitation that the evidential instances took place under conditions substantially similar to the one in issue.

But it was error to permit the defendant's expert witness to be asked, in an effort to impeach him, whether or not he agreed with certain medical works on which he had not relied as authority for his testimony. The witness, a physician, who testified that he had seen many men who had been gassed with chlorine and phosgene, and that there was no case on record in which it had been established that the inhalation of gas produced fibrosis (which the plaintiff claimed to have as a result of such inhalation), was asked, while under cross-examination, if he differed *with an author from whose book* counsel read statements opposed to the views of the witness. Objection was made, but the witness was required to answer. The vice of the question was that it involved the admission of hearsay evidence, without giving the adverse party an opportunity to cross-examine the author. It is well settled in New Jersey that when a physician testifies from his own experience as an expert, he may not be impeached by medical works on which he has not relied as authority for his testimony. It is only when a witness refers to them for his own opinions that they are receivable in evidence, and then only for the purpose of contradicting him. The federal court here was administering New Jersey law, and in doing so it must be governed by the New Jersey rules of evidence, unless there was a federal rule to the contrary. But the federal rule and the New Jersey rule are the same on this subject. This testimony was therefore inadmissible and prejudicial.

Validity of Regulatory Statutes

(Butcher et al. v. Maybury, Director of Licenses (U. S.), Fed. R. (2d) 155)

The United States District Court, W. D. Washington, S. D., in denying an application for an injunction, says that the plaintiffs were drugless healers and this suit was brought to restrain the enforcement of chapter 10 of the session laws of Washington for 1925, which statute provides for the revocation under certain circumstances of licenses issued to drugless healers.

The right of a physician to practice his profession is a property right, of which he cannot be arbitrarily deprived. The right is a qualified one, and is held in subordination to the duty of the state under the police power to protect the public health. The police power cannot be stipulated or bartered away. The authorities hold without dissent that it is competent for the legislature to prescribe qualifications for those who are to practice medicine and thus to assure that they shall possess the requisite character and learning. The regulation of drugless healers is a proper exercise of the police power. The regulatory power of the state may be properly committed to an administrative board or officer. These regulatory statutes may be made operative on those engaged in practice prior to the enactment of the statutes. The state may change the qualifications from time to time, making them more rigid. The legislature may prescribe qualifications, as to both character and learning, which will require those in practice to give up their occupation. Legislation prescribing qualifications which a practitioner cannot meet because of conditions antedating the enactment of the legislation is valid. Such legislation does not constitute punishment; it is legitimate regulation. The limitation on the foregoing doctrines is the principle that the regulations must be reasonable and must bear some relation to the service to be rendered by the practitioner.

The changes in the qualifications of drugless healers, made by the act of 1925, were within the legislative discretion. *It is not unreasonable to exact a high school education or* its equivalent as a proper standard of general education. Nor is it an arbitrary exercise of legislative power to require a residence course of three sessions, consisting of thirty-six weeks each, in a school of approved standing. The power of the state to require a license implies the power to revoke a license that has been improperly issued. Provision for the revocation of such licenses is made by the act of 1919, whose constitutionality was not under attack. The statute in question merely changes the procedure required for such purpose. The act of 1925 provides for notice and hearing to a licentiate whose license is proposed to be revoked. He is entitled to the compulsory attendance of witnesses and to be represented by counsel. If the issue is determined against him, he has a right to review the action of the director of licenses in the superior court of Thurston County. This procedure abundantly meets the "due process" requirements of the fourteenth amendment to the constitution of the United States. The equal protection of the laws guaranteed by that amendment is secured if the laws operate on all alike, and do not subject the individual to an arbitrary exercise of the powers of government. The statute in question operates alike on all who come within its purview. The presumption is that in its enforcement the director of licenses will act fairly and from a good motive.

*A bill of attainder is a legislative act which inflicts punish*ment without a judicial trial. The statute in question inflicts no punishment. If plaintiffs lose the right to continue the practice of their profession, it will not be as a punishment for some offense committed by them, but because their qualifications do not measure up to the legislative requirements. Nor does the statute in question fall within the classification of ex post facto laws. It has been expressly held that a statute that makes provision for the cancelation of licenses of those engaged in the practice of medicine is not obnoxious to the ex post facto provision of the federal constitution.

Improper Joining of Physicians as Defendants

(Wilder et al. v. Shannon (Ala.), 106 So. R. 69)

The Court of Appeals of Alabama says that there were two reasons why a new trial should have been granted in this case, in which Mrs. Shannon, as executrix, obtained a judgment for damages for the death of her husband in October, 1918, which she alleged was proximately caused by the negligence of the defendants in and about the treatment of her husband, as an employee of a railroad company. In the first place, it is well *settled in Alabama that in actions of this kind the plaintiff* carries the burden of proof to show by the evidence (1) negligence, and (2) that injuries suffered were the proximate result thereof. In neither particular did the plaintiff discharge that burden in the instant case. The overwhelming weight of the evidence was to the effect that whatever injuries the plaintiff may have suffered were the direct result of the unprecedented and little understood influenza epidemic that swept over the country at the time of the death of her husband. In the second place, the action was in tort and brought against the two defendants jointly. This court found nowhere in the record any evidence showing or tending to show any community of design or interest existing between them. Any wrong committed by either of them seemed to be entirely separate secting is done with very fine instruments, under a binocular dissecting microscope, the parts being placed in suitable clearing mediums and stained in toto; that is, the entire object (uterus, heart, stomach) is stained and dissected. A number of beautiful photographs show the remarkable results obtained by the macromicroscopic methods described. They clearly show, for instance, the ganglionic plexuses in the walls of the heart and the bladder, the nerves of the tendons, and the ganglion cells in the stomach walls. In short, the topography of final nerve ramifications and their relationship to the ganglionic system is brought out with remarkable clearness. It is unquestionably a highly scientific and useful book, well written and excellently edited.

Books Received

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for more extensive review in the interests of our readers and as space permits.

Chemistry in Agriculture: A Cooperative Work Intended to Give Examples of the Contribution Made to Agriculture by Chemistry. Edited by Joseph S. Chamberlain, Professor of Agricultural and Organic Chemistry, Massachusetts Agricultural College. Advisory Editor, C. A. Browne, Chief, Bureau of Chemistry, United States Department of Agriculture. Cloth. Price, $1. Pp. 384, with illustrations. New York: The Chemical Foundation, Inc., 1926.

Glorification of modern chemical advance by experts in various fields.

Puerperal Septicæmia: Its Causation, Symptoms, Prevention and Treatment. Being the Substance of a Thesis Submitted to the Royal Society of Medicine in June, 1924, and Awarded the Nicholls Prize. By George Geddes, M.D., C.M. Cloth. Price, $4. Pp. 200, with illustrations. New York: William Wood & Co., 1925.

Prize thesis reaching conclusion that only delivery by trained midwife in hospitals under medical supervision will lower still further deaths from puerperal sepsis.

Stauungstypen bei Kreislaufstörungen. Mit besonderer Berücksichtigung der exsudativen Perikarditis. Eine anatomische, experimentelle und klinische Untersuchung. Von Herbert Elias, Assistent an der I. med. Klinik, und Adolf Feller, Assistent am path.-anat. Institute. Paper. Price, 24 marks. Pp. 232, with 93 illustrations. Berlin: Julius Springer, 1926.

Research on exudative pericarditis and heart disease in general.

Nervous and Mental Disorders from Birth Through Adolescence. By B. Sachs, M.D., Consulting Neurologist to the Mount Sinai and Montefiore Hospitals, and Louis Hausman, M.D., Instructor in Neuro-Anatomy, Cornell University Medical College. Cloth. Price, $10 net. Pp. 861, with 110 illustrations. New York: Paul B. Hoeber, Inc., 1926.

Consideration from neurologic point of view of nerve disturbances with highly conservative discussion of psychologic and psychiatric problems.

The Diagnosis, Treatment and End Results of Tuberculous Disease of the Hip Joint. By George Perkins, M.Ch., F.R.C.S., Assistant Surgeon to the Royal National Orthopædic Hospital. Cloth. Price, $1.75. Pp. 118, with 32 illustrations. New York: Oxford University Press, 1926.

Monographic essay, emphasizing recumbency, traction and fixation, combined with open air, hygiene and heliotherapy for treatment.

Advising the Tuberculous About Employment. By W. I. Hamilton, Personnel Director, Boomer-Dupont Properties Corporation, New York, and T. B. Kidner, Institutional Consultant, Technical Adviser, Central New England Sanatorium Association Industrial Settlement. Cloth. Price, $2. Pp. 171. Baltimore: Williams & Wilkins Company, 1926.

Suggestions on the adjustment of the handicapped to their occupational environment.

The Private Practitioner as Pioneer in Preventive Medicine: Being the annual oration of the Hunterian Society, 1926. By Sir George Newman, K.C.B., M.D., D.C.L. Paper. Price, 30 cents. Pp. 47, with 1 illustration. New York: Oxford University Press, 1926.

Emphasizing life of John Hunter and showing how general practitioner has helped to build our knowledge of preventive medicine.

The Bacteriophage and Its Behavior. By F. D'Herelle, M.D., Director of Laboratories at Alexandria, Egypt. Translated by George H. Smith, Ph.D., Associate Professor of Bacteriology and Immunology, School of Medicine, Yale University. Cloth. Price, $8. Pp. 629, with illustrations. Baltimore: Williams & Wilkins Company, 1926.

The last word, concluding with a chapter on phagotherapy for dysentery and staphylococcus infections in which the author deprecates premature commercial exploitation.

Young's Practice of Urology. Based on a Study of 12,500 Cases. By Hugh H. Young and David M. Davis. With the Collaboration of Franklin P. Johnson. Volumes I and II. Cloth. Price, per set, $25 net. Pp. 1484, with 1003 illustrations. Philadelphia: W. B. Saunders Company, 1926.

A monumental text based on vast personal experience and research, beautifully illustrated.

An Introduction to the Study of X-Rays and Radium. By Hector A. Colwell, M.B., D.P.H., Director of the Radiological Department, King's College Hospital, and Cecil P. G. Wakeley, F.R.C.S., F.R.S., Assistant Surgeon, King's College Hospital. Cloth. Price, $3.35. Pp. 203, with 37 illustrations. New York: Oxford University Press, 1926.

Evidence of Injuries to Others—Use of Medical Works

(E. I. du Pont de Nemours & Co. v. White (U. S.), 8 Fed. R. (2d) 5)

The United States Circuit Court of Appeals, third circuit, holds that in this action, in which plaintiff White sued the defendant for alleged failure to take reasonable care to prevent the escape of noxious and poisonous gases in its factory where he worked, it was not error to admit the testimony of three other employees, who worked in the same rooms where he did, that the gases in those rooms produced practically the same effect on them as on him. In evidencing the quality of gas, such as phosgene and chlorine (to which the plaintiff alleged that he was subjected by the negligence of the defendant), by instances of its effects on others who worked in and inhaled it, the natural and logical limitation was that the evidential instances should have occurred under substantially the same circumstances; otherwise the ill effects might be attributed to the influence of some other element introduced by the differing circumstances. While in the use of this mode of proof unfair surprise and confusion of issues inevitably arise and often serve to exclude the evidence, yet the almost universal attitude of courts at the present time is to admit such evidence, subject to the limitation that the evidential instances took place under conditions substantially similar to the one in issue.

But it was error to permit the defendant's expert witness to be asked, in an effort to impeach him, whether or not he agreed with certain medical works on which he had not relied as authority for his testimony. The witness, a physician, who testified that he had seen many men who had been gassed with chlorine and phosgene, and that there was no case on record in which it had been established that the inhalation of gas produced fibrosis (which the plaintiff claimed to have as a result of such inhalation), was asked, while under cross-examination, if he differed with an author from whose book counsel read statements opposed to the views of the witness. Objection was made, but the witness was required to answer. The vice of the question was that it involved the admission of hearsay evidence, without giving the adverse party an opportunity to cross-examine the author. It is well settled in New Jersey that when a physician testifies from his own experience as an expert, he may not be impeached by medical works on which he has not relied as authority for his testimony. It is only when a witness refers to them for his own opinions that they are receivable in evidence, and then only for the purpose of contradicting him. The federal court here was administering New Jersey law, and in doing so it must be governed by the New Jersey rules of evidence, unless there was a federal rule to the contrary. But the federal rule and the New Jersey rule are the same on this subject. This testimony was therefore inadmissible and prejudicial.

Validity of Regulatory Statutes

(Butcher et al. v. Maybury, Director of Licenses (U. S.), Fed. R. (2d) 155)

The United States District Court, W. D. Washington, S. D., in denying an application for an injunction, says that the plaintiffs were drugless healers and this suit was brought to restrain the enforcement of chapter 10 of the session laws of Washington for 1925, which statute provides for the revocation under certain circumstances of licenses issued to drugless healers.

The right of a physician to practice his profession is a property right, of which he cannot be arbitrarily deprived. The right is a qualified one, and is held in subordination to the duty of the state under the police power to protect the public health. The police power cannot be stipulated or bartered away. The authorities hold without dissent that it is competent for the legislature to prescribe qualifications for those who are to practice medicine and thus to assure that they shall possess the requisite character and learning. The regulation of drugless healers is a proper exercise of the police power. The regulatory power of the state may be properly committed to an administrative board or officer. These regulatory statutes may be made operative on those engaged in practice prior to the enactment of the statutes. The state may change the qualifications from time to time, making them more rigid. The legislature may prescribe qualifications, as to both character and learning, which will require those in practice to give up their occupation. Legislation prescribing qualifications which a practitioner cannot meet because of conditions antedating the enactment of the legislation is valid. Such legislation does not constitute punishment; it is legitimate regulation. The limitation on the foregoing doctrines is the principle that the regulations must be reasonable and must bear some relation to the service to be rendered by the practitioner.

The changes in the qualifications of drugless healers, made by the act of 1925, were within the legislative discretion. It is not unreasonable to exact a high school education or its equivalent as a proper standard of general education. Nor is it an arbitrary exercise of legislative power to require a residence course of three sessions, consisting of thirty-six weeks each, in a school of approved standing. The power of the state to require a license implies the power to revoke a license that has been improperly issued. Provision for the revocation of such licenses is made by the act of 1919, whose constitutionality was not under attack. The statute in question merely changes the procedure required for such purpose. The act of 1925 provides for notice and hearing to a licentiate whose license is proposed to be revoked. He is entitled to the compulsory attendance of witnesses and to be represented by counsel. If the issue is determined against him, he has a right to review the action of the director of licenses in the superior court of Thurston County. This procedure abundantly meets the "due process" requirements of the fourteenth amendment to the constitution of the United States. The equal protection of the laws guaranteed by that amendment is secured if the laws operate on all alike, and do not subject the individual to an arbitrary exercise of the powers of government. The statute in question operates alike on all who come within its purview. The presumption is that in its enforcement the director of licenses will act fairly and from a good motive.

A bill of attainder is a legislative act which inflicts punishment without a judicial trial. The statute in question inflicts no punishment. If plaintiffs lose the right to continue the practice of their profession, it will not be as a punishment for some offense committed by them, but because their qualifications do not measure up to the legislative requirements. Nor does the statute in question fall within the classification of ex post facto laws. It has been expressly held that a statute that makes provision for the cancelation of licenses of those engaged in the practice of medicine is not obnoxious to the ex post facto provision of the federal constitution.

Improper Joining of Physicians as Defendants

(Wilder et al. v. Shannon (Ala.), 106 So. R. 69)

The Court of Appeals of Alabama says that there were two reasons why a new trial should have been granted in this case, in which Mrs. Shannon, as executrix, obtained a judgment for damages for the death of her husband in October, 1918, which she alleged was proximately caused by the negligence of the defendants in and about the treatment of her husband, as an employee of a railroad company. In the first place, it is well settled in Alabama that in actions of this kind the plaintiff carries the burden of proof to show by the evidence (1) negligence, and (2) that injuries suffered were the proximate result thereof. In neither particular did the plaintiff discharge that burden in the instant case. The overwhelming weight of the evidence was to the effect that whatever injuries the plaintiff may have suffered were the direct result of the unprecedented and little understood influenza epidemic that swept over the country at the time of the death of her husband. In the second place, the action was in tort and brought against the two defendants jointly. This court found nowhere in the record any evidence showing or tending to show any community of design or interest existing between them. Any wrongs committed by either of them seemed to be entirely separate and distinct from any committed by the other, and no reason appeared for joining them as defendants. A consideration of the whole record leads the court to the conclusion that the verdict and judgment for the plaintiff were founded in error, and ought not to stand.

Right to Have Expert Examine Injured Part Shown Jury

(Fleming et ux. v. Holleman et al. (N. C.), 130 S. E. R. 171)

The Supreme Court of North Carolina says that plaintiff Fleming, who was seeking to recover damages for personal injuries, while testifying that his injured leg was then swollen, pulled up his trousers and exhibited his leg to the jury. He also indicated a place between the knee and the ankle where the leg was broken. Then he said that there was a difference in the color of the two legs and that "when you press on this injured leg the dent will stay in, . . . the other leg is not like that. There is not much feeling in the injured leg. The most severe pain is right across here" (indicating broken place). After his testimony and that of one of the physicians who had treated him after the injury, the attorneys for the defendants tendered to the plaintiff two physicians and asked leave of the court for them to examine the plaintiff either in the presence of the injury or in a back room. Counsel for the plaintiff asked that this be done in the presence of the physician first mentioned. But the court declined to order the plaintiff to be examined, it appearing that one of the physicians selected by the defendants refused to go to the office of the plaintiff's physician, as there seemed to be some feeling between the two.

Under the facts and circumstances of this case, the supreme court thinks that the defendants had a right to have an expert examine the plaintiff's injured member. This right does not extend except to the injured member or part of the body that the plaintiff voluntarily exhibits to the jury. In the trial of all cases, the purpose is to ascertain the truth. The "inviolability of the person" is not lightly to be impinged; but, when a plaintiff voluntarily waives the inviolability by exposing his person to accentuate the damage, it is but justice that, at the instance of a defendant who may suffer by the exposure, there be expert examination.

Frequently attorneys representing opposing sides in injury cases agree to an examination in the interest of truth and justice, and the practice has become in recent years prevalent and to be recommended. This court has been unable to find any authority when this court has before passed on the question here presented. But, under the circumstances of this case, this court holds that, when the plaintiff voluntarily exhibited the injured member or part of the body to the jury, the defendants had a right to the examination. It is for the trial court in its discretion to allow the examination "under reasonable restrictions"—in the presence of the jury. One of the defendants' requests was "in the presence of the jury." The old saying is applicable: "What is sauce for the goose is sauce for the gander." This court thinks that the weight of authority permits expert examination before the jury under the facts here.

Action on Account for Services "by Order"—"M.D."

(Becker v. Humphries (Ga.), 130 S. E. R. 379)

The Court of Appeals of Georgia, division 2, in affirming a judgment in favor of plaintiff Humphries, says that he sued defendant Becker on an account for $570, and obtained a verdict for $310. The account was for $470 for "visits to J. D. Skinner on order," in December, 1918, and $100 for another physician, "to consultation to order of J. H. Becker." Counsel for the defendant contended that the petition failed to set forth a cause of action because there was no allegation that the plaintiff had been licensed to practice medicine in Georgia. But the court thinks that the allegation was unnecessary. In the first place, it appeared that the physician was located in the state of Florida, and the petition did not show that he practiced in Georgia. The account was for medical services rendered to one J. D. Skinner, without disclosing where they were rendered. So far as appeared from the petition, the patient may have been in Florida or elsewhere. But, regardless of this, it seems to be the rule that in an action by a physician for the value of professional services rendered by him it is sufficient to allege that he is a physician, that he was employed as such, that he rendered the services alleged, and that the reasonable value thereof was the amount sued for. By the weight of authority it was not necessary that the petition should go further and show that he had a license to practice according to the legal requirements of the state in which the services were performed. Of course, if it appears that the physician was practicing without a license, in violation of statute, he cannot recover. But this would ordinarily be a matter of defense. The copy of the account, which was expressly made a part of the petition, showed that the plaintiff was an "M.D.," and this court will take judicial notice that this abbreviation imports prima facie that the plaintiff was a physician.

Again, it was contended that it appeared from the petition that the plaintiff was claiming a liability against the defendant for professional services rendered to a third person, for which it was insisted that the plaintiff could not recover without showing an express agreement by the defendant to pay for the same. Even if so, the petition was sufficient to withstand the attack of a mere general demurrer based on this ground. It alleged that the defendant was indebted on the account, and that the services were rendered "on order," the reasonable inference being that the order was that of the defendant. Furthermore, suit on an open account may be sustained though the evidence shows an express agreement, where it is proved that the plaintiff has fully performed his part of the agreement and nothing remains to be done except for the other party to make payment. In the nature of the action it was not necessary for the plaintiff to allege an express agreement by the defendant to pay, irrespective of whether such agreement should be proved to entitle him to recover. As against the contentions which the defendant made the court holds that there was no error in overruling his general demurrer.

Then, while the evidence failed to show an express promise, the other circumstances in this case, as disclosed by the evidence, were sufficient to authorize an inference of an intention by the parties, at the time, that the services were to be furnished on the defendant's credit. It appeared that Skinner was living on the defendant's farm, but was not an employee. There was no relation between the defendant and the patient such as would raise a legal obligation on the defendant's part to procure and pay for the services of the physician for him. The preponderance of authority is to the effect that a mere request by one person to a physician to render services to another person, to whom the person making the request is under no obligation to supply the same, will not raise an implied promise, in favor of the physician, to pay for the services when rendered. A humane policy encourages the summoning by others of medical aid for those who may be stricken and unable to act for themselves. It would be quite easy in such a case for the physician to inquire whether the person making the request intends to become personally bound and when he fails to do so has no one to blame except himself for having acted on a mere request without an assurance that the party making it intends to incur a personal liability. The physician should remember that persons commonly call for medical aid for the sick solely out of a spirit of kindness, irrespective of relationship, and without any expectation of becoming personally responsible. But the instant case was not one of a mere request for the rendition of services and a compliance therewith by the physician. The circumstances authorized the inference of an intention that the defendant should be liable.

Sticking of Needle into Paralyzed Arm Before Jury

(Anthony v. Public Transit Co. (N. J.), 130 Atl. R. 895)

The Supreme Court of New Jersey holds that, in this action to recover damages for personal injuries where the plaintiff suffered a fracture of his right arm which subsequently resulted in a partial paralysis of the arm, it was not error for the trial court to permit a needle to be stuck into the arm in view of the jury to show that the plaintiff was suffering from paralysis and that his arm lacked sensation. This was a matter within the discretion of the court.

Society Proceedings

COMING MEETINGS

American Association of Industrial Physicians and Surgeons, Philadelphia, May 24-26. Dr. F. L. Rector, 22 East Ontario Street, Chicago, Secretary.
American Bronchoscopic Society, Montreal, Canada, May 29. Dr. Henry B. Orton, 671 Broad Street, Newark, N. J., Secretary.
American Dermatological Association, Philadelphia, May 27-29. Dr. C. Guy Lane, 416 Marlborough Street, Boston, Secretary.
American Laryngological Association, Montreal, Canada, June 3-5. Dr. George M. Coates, 1811 Spruce Street, Philadelphia, Secretary.
American Laryngological, Rhinological, and Otological Society, Montreal, Canada, May 31-June 2. Dr. Robert L. Loughran, 145 West 58th Street, New York, Secretary.
American Neurological Association, Atlantic City, June 1-3. Dr. Henry A. Riley, 870 Madison Avenue, New York, Secretary.
American Ophthalmological Society, Hot Springs, Va., June 14-16. Dr. Emory Hill, Professional Building, Richmond, Va., Secretary.
American Orthopsychiatric Association, New York City, June 5-6. Dr. Karl A. Menninger, Mulvane Building, Topeka, Kansas, Secretary.
American Otological Society, Montreal, Canada, May 31-June 3. Dr. Harold Walker, 390 Commonwealth Avenue, Boston, Secretary.
American Pediatric Society, Niagara Falls, Canada, May 31-June 2. Dr. Howard Childs Carpenter, 1805 Spruce Street, Philadelphia, Secretary.
American Psychiatric Association, New York City, June 8-11. Dr. Earl D. Bond, 4401 Market Street, Philadelphia, Secretary.
American Psychopathological Association, New York City, June 11. Dr. Sanger Brown II, 173 East 70th Street, New York City, Secretary.
American Surgical Association, Detroit, May 24-26. Dr. R. B. Greenough, 8 Marlborough Street, Boston, Secretary.
American Therapeutic Society, Philadelphia, June 10-12. Dr. W. J. Mallory, 1720 Connecticut Ave., N. W., Washington, D. C., Secretary.
Maine Medical Association, Poland Springs, June 10-12. Dr. B. L. Bryant, 265 Hammond Street, Bangor, Secretary.
Massachusetts Medical Society, Springfield, June 8-9. Dr. W. L. Burrage, 182 Walnut Street, Brookline, Secretary.
Medical Library Association, Ann Arbor, Mich., June 8-9. Miss Harriet Wilson, 535 North Dearborn Street, Chicago, Secretary.
Montana, Medical Association of, Billings, July 16-17. Dr. E. G. Balsam, 222 Hart-Albin Building, Billings, Secretary.
National Association for the Study of Epilepsy, New York City, June 7-8. Dr. A. L. Shaw, 108B The Albiston, Utica, N. Y., Secretary.
New Hampshire Medical Society, Concord, May 25-26. Dr. D. E. Sullivan, 7 North State Street, Concord, Secretary.
New Jersey, Medical Society of, Atlantic City, June 17-19. Dr. J. B. Morrison, 97 Halsey Street, Newark, Secretary.
North Carolina, Medical Society of the State of, Wrightsville Beach, June 15-17. Dr. L. B. McBrayer, Southern Pines, Secretary.
North Dakota State Medical Association, Minot, May 25-26. Dr. A. J. McCannel, Minot, Secretary.
Oklahoma State Medical Association, Oklahoma City, June 22-24. Dr. C. A. Thompson, 609 Barnes Building, Muskogee, Secretary.
Rhode Island Medical Society, Providence, June 3. Dr. J. W. Leech, 369 Broad Street, Providence, Secretary.
Texas, State Medical Association of, Houston, May 24-27. Dr. Holman Taylor, 207½ West 11th Street, Fort Worth, Secretary.
West Virginia State Medical Association, Morgantown, May 25-27. Mr. S. O. Neale, 211 Smallridge Building, Charleston, Executive Secretary.
Wyoming State Medical Society, Lander, July 12-13. Dr. Earl Whedon, Sheridan, Secretary.

MEDICAL SOCIETY OF THE STATE OF NEW YORK

One Hundred and Twentieth Annual Meeting, held at New York, March 30-April 1, 1926

(Continued from page 1577)

Experimental Production of Lung Abscess

Drs. Elliott C. Cutler, Simon A. Schlueter and I. F. Weidlein, Cleveland: Lung abscess can be reproduced in animals extremely well by the use of infected emboli, but we failed to produce lung abscess by the introduction of infected material and various types of organisms. In fifteen experiments not a single lung infection was produced. We believe that a certain number of postoperative lung abscesses may be due to infected emboli from the operative field. If this is so, such complications can only be reduced; they can never be totally avoided. The gentle handling of tissue, careful surgical technic and the greatest asepsis will reduce the morbidity from lung abscess.

DISCUSSION

Dr. James Morley Hitzrot, New York: I have long felt that aspiration does not explain the formation of these pulmonary suppurations as well as does embolism.

Dr. Howard Lilienthal, New York: The ordinary lung abscesses resulting from blood infection are multiple in character; those resulting from surgical operations (aspiration?) are usually single, or there are two or three discrete foci, sometimes on both sides, but ordinarily only in one lobe. That seems to me to be better explained by the inhalation theory than by the mere accidental entrance of organisms into the blood stream.

Dr. Paul W. Aschner, New York: One cannot explain the abscesses that occur in clean surgical cases on the basis of embolism because these emboli are aseptic. They produce ordinary infarction, and only rarely does secondary infection occur in an aseptic pulmonary infarction. Dr. Cutler's experiments are most ingeniously conceived and executed, but from a study of human pathologic material, I cannot subscribe to the view that postoperative lung suppuration is dependent, as a rule, on embolism.

Dr. M. C. Myerson, New York: I am strongly in favor of the aspiration route of infection. Pulmonary complications probably follow aspiration if there is some condition in the smaller bronchioles of the lung tissue that will prevent the expulsion of aspirated material. There is such a thing as congenital bronchiectasis, dry bronchiectatic cavities which exist unsuspected. It is on this lesion that a pulmonary suppuration may become superimposed in the presence of a general anesthesia.

Liver Function Studies

Dr. Charles S. McVicar, Rochester, Minn.: In studying liver function it must be remembered that laboratory tests supplement, but do not displace, clinical observation. Bile pigment is considered to be formed of broken down hemoglobin; that is, hemoglobin without iron. The product is manufactured by the reticulo-endothelial system, represented by cells of spleen and bone marrow. With the liver entirely removed, the bile pigment is formed but is not excreted; therefore the liver is mainly an excretory organ. In hemolytic jaundice there is more bile pigment formed than the liver can excrete, and the bile is dammed back into the blood stream. Tests for liver function include the Vandenburg test, which gives an estimate of the bilirubin curve in the patient and is used as an indication for or against operation; thus, a rising bilirubin curve indicates danger of congestion and hemorrhage and warns against operation; a declining curve shows indication for operation. The dye retention test does not coincide with the amount of jaundice, for with slight jaundice there may be considerable dye retention. In cirrhosis there is often much dye retention. The method of cholecystography is founded on the amount of dye excreted by the liver. The opaque substance is taken with the evening meal, and the time it takes to reach the gallbladder is estimated. A diseased gallbladder may partially fill, but in severe cases of liver obstruction the opaque substance does not reach the gallbladder. In such cases, intravenous glucose injection may prolong life. In regard to urea excretion tests, experimental work has shown that in severe cases of retention a limited nitrogenous intake is not called for.

DISCUSSION

Dr. Howard Shattuck, New York: Recent progress has enlarged our understanding of liver function, but much remains to be done. The quantitative estimation of bile salts in the blood is very much needed and will increase our understanding of the relation of the bile salts to liver disease. When surgical intervention is contemplated on the liver or bile passages, careful tests should be made, as we often see fatal results as a result of failure to comply with such a program. I should like to ask Dr. McVicar how often he sees cases of cholemia among the group of operative patients previously tested as he describes.

Dr. A. Diamond, New York: In making liver function tests we must allow for the fact that the liver possesses a large reserve of safety, and in speaking of one function we must remember that the liver accommodates itself to the performance of either function while the other is affected. Thus, in considering the Rosenthal-Rowntree method we must admit that in many instances it does not tell us what is taking place in the liver, but simply what dye cannot get through; the latter fact may be simply due to mechanical obstruction in the common duct or a growth in the ampulla of Vater. The improvement in the urobilogen test in the urine was worked out by Wallace and myself. It is important as a test f telling us what is taking place in the liver parenchyma, so that we can differentiate between mechanical obstruction in the common duct or that due to parenchymatous change in the liver, such as catarrhal jaundice. The urobilogen rises very high in the urine because there is never complete stenosis of the common duct. On the other hand, in carcinoma of the pancreas obstruction is complete and no bile gets into the intestine; therefore, no urobilogen is found in the urine. This is a simple test and can tell us promptly whether it is mechanical obstruction, such as carcinoma, or a catarrhal formation in the liver.

Dr. Charles S. McVicar, Rochester, Minn.: In regard to the question about cholemia, I did not mention cholemia and I do not know that I can discuss it. Undoubtedly there is a hazy condition of liver insufficiency which may be thought to be comparable to uremia, but it is not very clear cut. There is a condition of liver failure which is not due to hypoglycemia. The hepatectomized dog shows a certain decline of blood sugar, but patients rarely do. In regard to urobilogen, before we can assume results of these functional tests, we must first prove that urobilogen is formed in the intestine and also in the bile passages. Urobilogen is formed in the ducts, but may be it has to go into the intestine to be absorbed.

Neuron Block for Relief of Pain: Its Use in Angina Pectoris

Dr. George I. Swetlow, Brooklyn: This method has been used to relieve pain in angina pectoris, in the gastric crises due to syphilis, in pleurisy, in laryngeal pain due to tuberculosis, in cancer of the tongue, and in many other conditions. The work of neuron blocking is founded on the anatomic basis that the nerves of the various sympathetic ganglions enosculate with one another. If certain fibers are extirpated, others will take it up and the irritation will pass into the centers of consciousness in the form of pain. There is pain in the skin area supplied by the dorsal root which is adjacent. Therefore, if one can locate the dorsal root ganglion that is receiving the painful stimulation one can intercept the painful stimulus from entering the spinal cord, and thus prevent its reaching the brain. This method was tried in eight patients suffering from severe cardiac conditions, six of whom had coronary thrombosis. Four patients died later, but they were in very serious condition. In the cases of gastric crises, the painful stimulus starts in the epigastric plexus. Injection of the dorsal root here gave good results in preventing pain. In cases of severe pleuritic pain in tuberculosis or carcinoma of the pleura, the pain was relieved. In one case, cancer of the tongue, the pain was not relieved.

DISCUSSION

Dr. John Wyckoff, New York: The criticism aimed at this method is that it does not cure; it is merely palliative. In regard to any measure of this kind we have to ask ourselves: 1. What is the inconvenience or danger? 2. What is the quantitative or qualitative relief? If the relief is not greater than the danger or inconvenience, then relief is of no value. With the use of surgery, the danger or inconvenience to most patients is greater than the relief received. The patients, even if relieved of pain, must die eventually; therefore this procedure does not lengthen life. The physician must consider that the patient is suffering from a malady in which sudden death is likely to occur, and he must be willing to bear the brunt of criticism if the patient dies suddenly after such treatment has been tried.

Dr. Alexander Lambert, New York: Many more people are arriving at years of senescence; therefore there are many more suffering from cardiac symptoms than formerly. We may be able to give relief from pain to many of these people, if we cannot do more for them. The pain in the anginal syndrome is not due to a similar process in all cases. To understand the anginal syndrome we must study the sympathetic system as part of the general nervous system. It has its efferent and afferent fibers, but the gangilons are motor ganglions and are out at the periphery. Therefore, to stop the pain one must reach the posterior root of the spinal nerve and at that point one can head off the pain before it reaches the thalamus. This is where Dr. Swetlow's procedure is of use. Operations on anginal patients have succeeded in some cases; in some they have failed because of the fact that every nerve is not the same in every man. The superior cardiac nerve of the sympathetic has been cut and has stopped the pain in some cases. When one cuts off the superior sympathetic ganglion one cuts off the ganglion of several sympathetic centers, such as the high carotid sphenopalatine ganglion, which is a very valuable portion of the sympathetic and should not be lightly discarded. Therefore blocking is better than taking out what cannot be replaced. One strikes at the accessory fibers of the heart which help in the conductivity and contractility of the ventricles, and one leaves the heart with inhibitory fibers. The result of this is that the patient dies with great edema of the lung. The superior thoracic ganglion should not be touched at all. Something very valuable has been cut off, but one can cut above that. One can cut off afferent fibers that go to the vertebral arteries. In such a case blocking is wiser than cutting. When there is pain coming from coronary disease, the afferent fibers can be cut out. If there is pain in the epigastrium and in the arms, it comes from the same dorsal segments that the splanchnic supplies and cannot be reached. They go behind and cannot be blocked off. About 10 per cent of coronary patients have pain in the arms. In 300 cases of coronary thrombosis only 25 per cent gave previous warning that they had cardiac disease; but when the pain is intense it is worth while to take the chance of blocking the impulse before taking the chance of cutting with the possible result of edema of the lung.

Chronic Nephritis

Dr. Nellis B. Foster, New York: Heart disease heads the list of causes of death. It is often combined with chronic nephritis. Recognition of this condition in hospital patients *is not enough. The treatment at that stage is merely palliative.* The disease has then been of long duration because the subjective symptoms are slight and the disease escapes early detection. Life insurance companies discover many early cases, and make a practice of rejecting patients who show an albuminuria. The insurance companies can prove that there is an earlier death rate among persons showing albuminuria, although, if it occurs before 30, it is as likely to be tuberculosis as nephritis. After 40, no case of albuminuria can be dismissed even if there is no sign of elevation of blood pressure. Insurance figures show that an increase of 10 degrees in blood pressure is equal to an increase in mortality rates of from 10 to 14 per cent.

DISCUSSION

Dr. John A. Lichty, Clifton Springs, N. Y.: The family physician has been impressed that the study of urine is a very complex matter requiring chemical apparatus, so that he avoids doing the very simplest test to determine whether or not the patient has nephritis. From the time of Bright to the present day, the studies in kidney disease have centered largely about the other elements of the urine, such as albumin, casts, various cells, uric acid, urea toxins, and the elimination of dyes. After this came the chemical studies of the blood, including urea, uric acid and creatinine, all interesting and somewhat helpful, but none giving any earlier evidence of chronic nephritis than the study and comparison of the day and night urine—the so-called fixation and concentration test. Dr. Roger Hubbard recently completed an extensive study of seventy cases of nephritis of all forms, applying all the tests in common use, and in some of which necropsies were done, with the result that there was revealed an interesting sequence of positive findings as the disease progressed; but not a single test gave earlier evidence of kidney disease than the fixation and concentration test. In fact, it seemed that the more difficult and complex the test the less helpful it was in showing early involvement of the kidney. If the purpose is only to determine the margin of safety for a patient undergoing the stress and strain of disease or experiencing the ordinary crises of life, most of the reliable tests for kidney function may be of use; but the test which gives the earliest evidence of kidney disease is the one most desirable.

*Standardization of Tuberculin. J. D. Aronson, Philadelphia.—p. 263.
Extent of Normal Variability of Vital Capacity of Lungs of Children. C. A. Stewart, Minneapolis.—p. 272.
Vital Capacity of Lungs of Children Having Masked Juvenile Tuberculosis. C. A. Stewart, Minneapolis.—p. 278.

Limited Miliary Tuberculosis.—In Falisi's case the original focus of tuberculosis was an apparently small but active lesion in the right lung. From this hematogenous dissemination, the disease was apparently limited to the choroid plexus and base of the brain.

Recovery from Tuberculous Meningitis.—The case recorded by McMahon was typically clinical meningitis in its onset and symptomatology. The presence of tubercle bacilli in the spinal fluid, as shown by animal inoculation, proved it to be tuberculous. The unusual features were the number of exacerbations and remissions. The disappearance of tubercle bacilli from the spinal fluid suggested circumscription and encapsulation of the lesions. The small number of bacilli and the absence of meningeal hypertension indicated that the lesion was not predominantly of the exudative type, but possibly proliferative in character.

Pneumoperitoneum in Treatment of Tuberculous Peritonitis.—Guilbert has treated four cases of tuberculous peritonitis with serous effusion by aspiration of the fluid and the introduction of filtered air. These patients have remained well and are working, one after five years, and one for nearly two years. The remaining two cases are very recent ones. In one case both a pneumoperitoneum and a pneumothorax have been done. Guilbert has also used pneumoperitoneum in connection with laparotomy in two cases of advanced tuberculous enterocolitis, with apparently some relief but no permanent benefit, as both patients died.

Standardization of Tuberculin.—The strength of nine samples of commercial tuberculin and one sample of standard tuberculin was determined by Aronson by means of the intracutaneous injection into tuberculous guinea-pigs, and compared with their toxicity for tuberculous guinea-pigs, with complement fixation, and with the precipitin reaction. These samples of tuberculin varied greatly in strength.

*Metabolic Aspects of Calcium Therapy. A. P. Briggs, St. Louis.—p. 440.
*Effects of Intravenous Injections of Acriflavine in Sepsis. C. F. Tenney and J. Lintz, New York.—p. 445.

Experimental Renal Insufficiency.—The purpose of Anderson's study was (*a*) to determine the blood pressure changes in low renal function or insufficiency and (*b*) to determine the possible influence of high or low protein diet on the course of chronic renal disease. He found that removal of two thirds of the kidney substance in rabbits results in a retention in the blood of urea and creatinine, which either increases progressively in intensity until death results, or decreases progressively until normal values are once more attained. A high protein diet causes hypertrophy of the kidneys in normal rabbits not operated on, but no further change in the kidney remnant than to further augment the hypertrophy. A high protein diet causes a retention of creatinine and urea in the blood in rabbits from which a portion of kidney substance has been removed. It is proportionate to the amount of kidney that has been removed. Hypertension is not caused in rabbits by renal insufficiency per se, nor by a high protein diet, even in the presence of a low renal function, nor by prolonged retention of creatinine and urea in the blood. The high protein diet here give results in a marked atherosclerosis of the aorta which do not extend to the small arteries. These changes in the aorta do not result from low renal function or from prolonged retention of creatinine and the urea in the blood.

Copper Poisoning Causes Hemochromatosis.—Mallory points out that evidence is slowly but steadily accumulating in favor of the view that chronic poisoning with copper causes the symptom complex known under the different names of hemochromatosis, bronzed diabetes and pigment cirrhosis. Copper is an exceedingly useful and indispensable metal in many ways, but it should not be employed where it may come in contact with foods or drinks, especially if they contain acids of any sort, because it is so readily dissolved by many of them. This would exclude its use for cooking utensils of any sort, for shakers of cocktails and acid drinks, and for the worms of the condensers in stills. Its use in pipes for drinking water and for hot water heaters is probably without danger.

Carcinoma of Liver.—Five cases of primary carcinoma of the liver are described by Counseller and McIndoe. Four were hepatomas or primary carcinomas of the liver cells, and one was a cholangioma or carcinoma of the bile ducts. These cases occurred among 5,976 necropsies, together with 220 cases of secondary carcinoma of the liver and 127 cases of portal cirrhosis. The five cases reported were associated with intrahepatic metastasis by way of the portal and the hepatic veins, but in only two cases were extrahepatic growths present. All the cases were associated with cirrhosis of the portal type. The histories in three cases point to a preceding cirrhosis, and in all these cases the microscopic examination of the connective tissue indicated a long standing process. The relation between the hyperplastic liver tissue and the malignant cells is emphasized. The authors believe that from 3 to 4 per cent of cases of cirrhosis, particularly of the portal type, will become carcinomatous.

Cholecystography and Liver Disease.—The results noted by Fried and Whitaker have shown that a moderately damaged liver does not interdict the use of sodium tetraiodophenolphthalein. The existence of presumed or obvious hepatic disease in man should not necessarily preclude the employment of the drug for purposes of cholecystography in the clinic.

Treatment of Carbon Monoxide Poisoning.—There is a difference of opinion as to the relative value of the different treatments of carbon monoxide poisoning. Walton and his associates endeavored to determine relative values by means of experiments on dogs. It was found that in dogs suffering from carbon monoxide asphyxia the difference in elimination time between oxygen treated and oxygen plus 5 per cent carbon dioxide treated subjects is slight. Since the rate of elimination under pure oxygen is almost as rapid as with the oxygen plus 5 per cent carbon dioxide, and since the oxygen treatment is more readily obtainable, it is recommended that its use be continued, particularly in localities where transportation is difficult. The air plus 5 per cent carbon dioxide treatment should be of value for rescue parties sent to inaccessible mines, and especially in military operations.

Enzymic Activity of Ingested Pancreatin.—Aaron et al. concluded that a properly prepared and ingested pancreatin solution will pass through the stomach rapidly enough to insure the retention of a considerable portion of its original proteolytic, lipolytic and amylolytic activity when it reaches the duodenum.

Iodine Test of Pancreatic Function.—Piersol et al. used the Barsler test but modified it by increasing the amount of iodine solution added to each of the ten tubes by 0.05 cc. (1 drop) so that 10 drops, or 0.5 cc., are added to the tenth tube. It is asserted that with the modifications it has been possible to obtain consistent results from day to day on the same patient even though the iodine absorption factor varied greatly.

Metabolic Aspects of Calcium Therapy.—Briggs asserts that calcium acetate given by mouth causes the diversion of a considerable amount of the excreted phosphoric acid from the urine to the feces. The relief from this phosphoric acid load necessitates the synthesis of a smaller amount of ammonia by the kidney. The administration of calcium acetate affords a means of correcting the phosphoric acid retention in nephritis free from the disadvantages of alkali retention and resulting edema which is observed with sodium bicarbonate therapy.

Effect of Acriflavine on Sepsis.—Of eleven patients with generalized infection who were treated by Tenney and Lintz with intravenous injections of neutral acriflavine, six had positive blood cultures. Of these six, five died despite the treatment. The sixth case, one of typhoid fever, ran the usual course, and showed no shortening of the time necessary to procure negative stool cultures for release from quarantine. The authors have seen no improvement following the intravenous use of neutral acriflavine in cases of sepsis or bacteremia. There was spontaneous recovery in two cases of *Streptococcus hemolyticus* sepsis.

Difficult Urination Associated with Intracranial Tumors of Posterior Fossa. E. Holman, Cleveland.—p. 371.

Encephalitis Periaxialis Diffusa.—Study of the case reported by Brock et al. throws light on the pathogenesis of the disease. It evidently began in the occipital lobes, although not at the extreme tip. The disease was bilateral and evidently spread forward by continuity. The peculiar "large globoid cells" observed in this disease resemble endothelial cells, and it is possible that they are associated with the proliferation of blood vessels that takes place in the affected regions.

Escape of Cerebrospinal Fluid Through Nose in Cases of Increased Intracranial Pressure.—In every one of the series of proved cases studied by Locke, spontaneous cerebrospinal rhinorrhea was associated with internal hydrocephalus and increased intracranial pressure. The most common lesion which produces a combination of these two factors is a cerebral neoplasm, but inflammatory or congenital obstruction of the cerebrospinal fluid also may be responsible. In this series the communication between the nose and the cerebrospinal fluid pathways occurred through the cribriform plate.

Bulbocapnine.—Bulbocapnine is one of eleven alkaloids from *Corydalis cava*. Bulbocapnine will cause a cessation of tremor in many cases of paralysis agitans. The treatment is palliative, but not curative. The experimental work done by Mella on animals seems to indicate that bulbocapnine may also be of value in the experimental study of catatonia.

Cerebrospinal Fluid Not Oxytocic.—Of twenty-eight cerebrospinal fluids obtained by Shapiro from twenty-five different patients, none caused an oxytocic effect on the virgin guinea-pig uterus. On the contrary, he observed a tendency of these fluids to inhibit contraction of the isolated uterus of the guinea-pig. He failed to obtain evidence to show that the intravenous injection of pituitary extract causes an increased secretion of the active principle present in the posterior lobe of the hypophysis into the cerebrospinal fluid within three minutes after the injection.

Toxemias in Early Stages of Mental Disease.—Evidence is presented by McIntyre et al. to show that manic-depressive, schizoid and confusional reactions may, in their early stages, be accompanied by signs of toxemia: leukocytosis, acidosis, fever and nitrogen retention. Treatment directed toward the elimination of the toxemia is frequently effective in bringing about a mental recovery. The toxins, acid or otherwise, so affect the hydrated colloids of the nerve cell as to bring about a cracking of the emulsion of which the nerve cell is composed. Treatment to be effective must take place before this irreversible cracking point is reached.

Spinal Fluid in Epilepsy.—An examination of fifty spinal fluids of epileptic patients, made by Patterson and Levi to determine whether such fluids exhibit any abnormalities, in the main was largely negative.

Xanthochromia in Epidemic Encephalitis.—Of thirty-two patients with epidemic encephalitis made the subject of study by Rothschild, three, or 9.38 per cent, showed xanthochromic spinal fluid.

*Four Unusual Malignant Tumors of Liver. L. W. Smith, Boston.—p. 365.
Recurrent Lipomatous Tumors of Groin. Liposarcoma and Lipoma Pseudomyxomatodes. R. H. Jaffé, Chicago.—p. 381.

Biometric Studies in Pathology.—A detailed account is presented by Pearl and Bacon of the biometric characteristics of the age, sex and racial distributions of persons included in 7,500 necropsy records. The data presented afford the requisite statistical basis for special biometric studies of particular pathologic conditions.

Increase in Insular Tissue of Pancreas in Child of Diabetic Mother.—A case is reported by Gray and Feemster in which the pancreas of a child born of a diabetic mother contained approximately twenty-four times as much insular tissue as the normal pancreas. The increase in maternal blood sugar is suggested as the stimulus which called forth the increase in insular tissue in the pancreas of the child. It is further suggested that hypoglycemia, the result of this insular hypertrophy and hyperplasia, may play a rôle in the sudden death of the baby. Associated with the hypertrophy of the islands of Langerhans was a hypertrophy of many medullary cells of the suprarenals.

Splenectomy for Thrombopenic Purpura.—The beneficial influence of splenectomy on extremely severe acute essential thrombopenia is shown by the case reported by Alrutz, Nortell and Piette. In about four and a half months the blood platelet count rose from 15,000 to 210,000. The erythrocyte count rose from 3 million to 4 million; the leukocyte count from 7,250 to 8,700. The differential count was within fairly normal limits.

Malignant Tumors of Liver.—Four unusual malignant tumors involving the liver are presented by Smith: (1) a primary hepatoma in a girl of 10; (2) a metastatic leiomyosarcoma in a woman of 50; (3) a primary melanoma of the liver in a woman of 68, and (4) a probable angiosarcoma in a woman of 36.

Hypertonic Saline Injections in Adynamic Ileus.—Ross asserts that animal experiment and clinical proof justify the intravenous administration of hypertonic saline solution in this condition. Results may be expected where other known agents fail.

Researches on Pernicious Anemia.—Montgomery discusses the activities of the Medical Research Committee of the University of Manitoba in promoting the work being done under the "Gordon Bell Memorial," established in 1924, by the College of Physicians and Surgeons of Manitoba, in studying the etiology of pernicious anemia.

Chloride Metabolism in Pernicious Anemia.—Rioch and Cameron report on some of their work done in the study of sixteen cases of pernicious anemia in the active phase and ten cases in remission. None showed the presence of hydrochloric acid in the gastric secretion. Evidence is adduced *that in pernicious anemia not only is there complete gastric* achlorhydria, but further, that in some, if not all, cases, the chloride ion is absent from such gastric secretion as may occur. In six cases of pernicious anemia examined for peptic activity, three showed no activity, two very slight activity, and in one the activity was somewhat below normal. The dependence of the value of whole blood chloride on the *proportion of* cells to the plasma is emphasized. Determinations of whole blood chlorides are valueless for most clinical purposes. The plasma chloride content is relatively constant in the anemias. In the active stage of pernicious anemia, especially when the hemolytic changes precede nervous symptoms, there is a slight but undoubted lowering of cell chlorides. In the remissive stage of pernicious anemia, and in the other anemias studied, the average figure for cell chlorides does not markedly differ from the normal, but the extremes show wider variations. There is in the active stage of pernicious anemia a marked upset in chloride metabolism, characterized by lowering of the blood cell chlorides, and in some, if not all, cases, by the absence of the chloride ion (as well as hydrochloric acid) from any gastric secretion that occurs. The former abnormality may disappear in the remission stage.

Arteriotomy for Obstruction by Embolus.—Under local anesthesia, MacDougall removed an embolus about seven-eighths inch (2.2 mm.) long and weighing 27 grains (1.8 Gm.) from the common femoral artery of a man, aged 65. The embolus was lodged at the bifurcation of the common femoral and for three-fourths inch (19 mm.) above it. The result was a perfect one in every way.

Lipodystrophy and Hyperthyroidism.—Progressive lipodystrophy, cephalothoracic lipodystrophy, or syndrome of Barraquer-Simons (syndrome rather than a disease), appears to be a predisposition to a peculiar way of losing flesh, determined by neurovegetative factors whose nature is not known. There are cases, chiefly in women, in which this alteration is what might be called a physiologic or attenuated form. If in such predisposed cases there is an additional cause for losing weight, such cause will act as an "activator" which will accentuate the typical form of loss of flesh. Among these, in the opinion of Marañon and Soler, the most frequent is hyperthyroidism, undoubtedly because it coincides with favorable neurovegetative perturbations which determine the lipodystrophic predisposition. Cephalothoracic lipodystrophy frequently coincides with hyperthyroidism, and in every case of lipodystrophy the minor hyperthyroid symptoms should be sought and the basal metabolism be determined; also in every case of adiposis. In the lower parts the fat is normal, or at least offers a greater resistance to the loss, especially if lipomatotic formations are produced, as is frequently the case.

Thyroid, Parathyroid and Growth.—Hammett presents data bearing on the salient sex and systemic similarities and differences in growth response to thyroid and parathyroid deficiency initiated at different stages of development in the life of the albino rat, so far as growth in body weight, body length and tail length is concerned.

Thyroid, Parathyroid and Estrus.—Data presented by Lee seem to show that the effects of thyroidectomy and of parathyroidectomy on the estrual cycles seem to be additive when both operations are performed on the same animal.

Chloroma.—Seventy-three cases recorded in the literature are analyzed by Brannan and one personal case is reported. This case in most respects was typical of chloroleukemia. The patient was a young man suffering from myelogenous leukemia with gradually developing and characteristic, hard, flat cranial tumors, exophthalmos with marked visual and fundus changes, facial paralysis, impairment of hearing and symptoms confused with mastoiditis and otitis media. There was marked roentgenologic evidence of intracranial pressure and orbital and sinus growths. The leukocyte counts, which ranged from 12,000 to 39,900, were relatively low for leukemia but rather typical of chloroleukemia. The leukocytes at first were largely metamyelocytes but later mostly myeloblasts. Marked secondary anemia, with evidence of regeneration of the erythrocytes, was a characteristic feature. A very detailed postmortem examination was made.

Interagglutination of Maternal and Fetal Blood.—The isoagglutination characteristics of the bloods of 375 normal and of 104 toxemic women and their newly born infants have been studied by Allen. There was no evidence that incompatibility is more frequent in toxemic than in normal gestation. Incompatibility between the bloods of mother and infant was present in 20.8 per cent of 375 normal and 21.1 per cent of 104 toxemic pregnancies. There was no evidence of an increased titer in the maternal serum of toxemic women, nor of specific immunization of the mother against fetal corpuscles. This series of cases gives no evidence that the late toxemias of pregnancy have their origin in iso-agglutination phenomena.

Basal Metabolism in Toxemias of Pregnancy.—Stander and Peckham failed to find basal metabolism determinations of any real help in differentiating between the various types of toxemias in late pregnancy. In normal pregnancy, as well as in the different toxemias of pregnancy, there is some factor or factors, which result in an elevated basal metabolic rate as term is approached, a gradual return to normal ensuing during the puerperium. It is probable that such a factor, or factors, may have to do with the growing product of conception, as well as a slight increased activity of the thyroid gland.

Stovarsol in Experimental Syphilis.—The sodium salt of acetyl oxyaminophenylarsine acid, given by mouth in a single dose of 0.5 Gm. per kilogram, Poole says, appears to exert a definite prophylactic action in experimental syphilis of the rabbit. In the same dosage, it apparently can bring about the healing of the initial syphilitic orchitis. The drug is toxic for rabbits in single doses as low as 0.2 Gm. per kilogram, when administered by mouth, causing death of the animal within twenty-seven days or less. Further experimental study of the drug is advised by Poole before it is employed in human syphilis.

Treatment of Accidental Wounds.—The treatment advocated by DeMotte consists in assisting nature to heal, and refraining from the use of antiseptics, as they really have little value in these cases. Nature prevents infection mechanically by hemorrhage, chemically by antisepsis, and biologically by phagocytosis. Blood washes out the wound, carrying away a certain amount of foreign matter, including bacteria. The blood contains certain antibodies which act as chemical antiseptics and kill bacteria, and leukocytes which engulf and digest them. Nature repairs a wound by bathing the injured tissues with serum which contains cell food, and leukocytes which digest and absorb badly damaged tissue. On this basis the treatment employed is as follows: (1) Thorough cleansing of the surrounding skin; (2) trimming away of overhanging, ragged skin margins; (3) gentle, but thorough sponging out of the wound, removing blood clots and foreign matter; (4) trimming away of all badly damaged tissue in the depth of the wound. This opens all capillaries and tissue spaces for the flow of serum. (5) Drainage strip, if needed; (6) closure with judgment by adhesive strips or sutures; (7) moist dressings, if needed; (8) continuous moist heat in the more extensive wounds. If wounds are handled in this manner, Nature will disinfect them in forty-eight hours and healing will occur with a minimum of scar tissue.

Staining Tubercle Bacilli.—An examination made by Corper of twenty sputums containing tubercle bacilli by thirteen different methods revealed that when the technic is properly performed the majority of these methods may result in staining the tubercle bacilli in the sputums with equal efficiency. There was, however, a decided difference in the ease of performance, speed and simplicity of the various individual methods. Sixteen different positive smears consecutively stained and restained (after destaining) by nine different methods emphasized further the importance of technic in the staining of tubercle bacilli. For practical purposes the simple, steaming, carbolfuchsin (Ziehl-Neelsen) method, or one of its modifications, is recommended. The choice of colors remains with the individual operator, since any number of dye combinations can be used for staining and counterstaining the tubercle bacilli. A negative finding by the method requires for further elaboration animal (guinea-pig) inoculation. In view of the danger of technical errors and in order to raise the present efficiency of the technic, especially with otherwise negative findings or when only single specimens are available, it is recommended that each specimen tested for tubercle bacilli by staining methods be controlled by the coincident staining of a like preparation to which a standard suspension of tubercle bacilli, which can easily be kept available in the laboratory at all times, has been added.

Reactions of Typhoid Vaccination.—Nichols and Hitchens assert that recent advances in dealing with antitoxic immunity as seen in diphtheria and scarlet fever have not been duplicated in regard to bacterial immunity as seen in typhoid fever. It is not possible at present to detect susceptibles and immunes to typhoid by skin or other tests.

Influence of Magnesium Sulphate on Bile Expulsion.—Ganit and Volborth found absolutely no influence of magnesium sulphate on the expulsion of bile into the duodenum.

Variations in Blood Sugar Caused by Insulin.—John asserts that the amount of insulin administered intravenously appears to bear no regular relation to the fall of blood sugar. While the administration of insulin usually produces a decrease in the blood sugar, in some instances it is followed by an increase which may or may not be related to postprandial hyperglycemia. In general, whatever the primary effect of insulin, repeated doses result in a decrease in the blood sugar; this apparently cumulative effect, however, is independent of the size of the doses. The level of blood sugar per se is not a criterion of the probability that a reaction will follow the administration of insulin. Thus, a large dose of insulin may be given in the presence of hypoglycemia without any resultant reaction; and, in another case, a reaction may occur in the presence of a marked hyperglycemia.

Problems in Insulin Therapy.—Mallory and Roe insist that in a patient apparently not responding to increasing doses of insulin by a proportionate decrease in sugar excretion and reduction of the blood sugar level, the time relation of sugar excretion to insulin dosage should be investigated. The simplest method is the examination of three-hour portions of urine. Frequent blood sugar determinations give additional information. The remedy is the redistribution of insulin in amount and at the time when required.

Pleurisy and Tuberculosis.—Of 1,182 patients with tuberculosis, whose histories were reviewed by Hastings, fibrinous pleurisy and pleurisy with effusion occurred in 55.7 per cent. Hastings feels that this means that fibrinous pleurisy may be the first symptom of pulmonary tuberculosis; hence, patients with fibrinous pleurisy should be warned that they may have tuberculosis.

Flocculation in Tuberculosis.—Hardesty prefers the Baum technic. He has carried out the reaction in 300 cases, comprising patients and employees of a sanatorium, and guinea-pigs, healthy and diseased. Strongly positive reactions have occurred only in tuberculosis. The intensity of the reaction is roughly proportional to the extent and activity of the process. Weak positives are occasionally found in those with mild tuberculous infection and in individuals presumably healthy. Negative reactions occurred only once in active tuberculosis. Thus, it would seem that one great value of the reaction consists in its power to differentiate between active tuberculosis in which the bacilli are not found, and other diseases which clinically simulate it.

Diet in Tuberculosis.—Myers urges that the diet of the tuberculous patient must be prescribed by the physician, just as drugs are prescribed in certain other diseases. He objects to forced feeding and stresses the importance of meeting the vitamin requirement of the body.

Thoracoplasty in Tuberculosis.—Law has done fifty-eight operations on thirty-one patients and has lost only one directly from the operation. This was a one-stage operation, and the man died of shock. In all cases he has used local nerve block with procaine supplemented by nitrous oxide gas and oxygen analgesia.

*Treatment of Laryngeal Tuberculosis. R. S. Moore, Syracuse.—p. 247.

Lymphatic Drainage.—The operation of draining the thoracic duct in the neck is a surgical procedure which is designed to overcome the septic absorption which occurs in diffuse peritonitis. The operation is described in detail by Costain, and sixteen cases are reported. The mortality rate of these cases has been reduced from 30 to 40 per cent.

Botulism.—A case of botulism, fatal in five days, due to eating home canned string beans, is presented by Foord and Forsyth. *Bacillus botulinus*, type B, was recovered in pure culture from the spoiled beans, and from the intestinal content of the patient at necropsy. Toxin production by the organism was vigorous. Chickens were immune to enormous doses of the same, whereas guinea-pigs and rabbits were highly susceptible. Heating the toxin in boiling water for five minutes destroyed it completely. Pathologic findings were characteristic of botulism in the patient as well as in the animals.

Laryngeal Tuberculosis.—Moore pleads for a more systematic study of the larynx in all cases of tuberculosis, followed by an examination at least once each month.

Relation of Social Settlement to Community Life. G. T. Fergusson.—p. 129.

Community Control of Rickets.—The New Haven demonstration was undertaken to show that 90 per cent of the babies seen showed the evidences of slight rickets by roentgen-ray examination before they were 6 months of age. When the directions regarding cod liver oil and sunbaths were followed regularly, these babies did not develop the slightest evidence of rickets; that is, the disease was controlled. In contrast to this group stand the control series which showed 18 per cent of moderate or marked rickets at 10 months, 25 per cent at 13 months, and 37 per cent at 25 months of age. In the temperate zone, rickets is a nearly universal disease among infants, whether breast fed or artificially fed. If prevention is to be brought about, Eliot says, antirachitic treatment should be begun in the first month of life and continued faithfully throughout two years.

Surgical Disease Mortality.—Data obtained by Willis from the Bureau of Vital Statistics show that the number of deaths per hundred thousand from gallstones increased 77 per cent since 1901; the mortality rate from gastro-intestinal ulcer has increased 72 per cent; that from appendicitis almost 31 per cent, while the mortality rate accompanying thyroid disease increased more than 250 per cent. Willis believes that standardization of the methods of treatment of these diseases will effect a material reduction of these mortality rates.

Intrahepatic Cholelithiasis.—The unique features in the case reported by Judd and Burden are: The finding of many large intrahepatic calculi in a liver that was grossly normal, more than eleven years after cholecystectomy, and removal of numerous stones from the extrahepatic ducts; and the presence of this condition without the occurrence of jaundice or any clinical evidence of hepatic insufficiency, the condition being an incidental finding in a patient who died from intestinal obstruction.

Demonstration of Median Nerve Lesions.—The sign described by Crile presents the means of delineating in a graphic manner cutaneous areas, the nerve supply of which is blocked. It was first noted in a case of malunion of a fracture of the lower end of the radius and ulna with complete sensory paralysis of the median nerve area in the hand. As part of the treatment, Bier's hyperemia was employed. The patient noticed that after the hyperemia had been established for two or three minutes, the hand assumed a peculiar appearance. The thumb and first two fingers and the radial side of the ring finger gradually became cyanosed and tense, the color extending over the thenar eminence and outlining the sensory distribution of the median nerve. The rest of the ring finger and the little finger and the remaining area of the palm became a mottled red. As long as pressure was maintained, the appearance of the hand remained unaltered when the pressure was removed, the hand gradually assumed its normal color. This phenomenon became less marked in degree and extent as the nerve function returned. After six weeks, sensation had returned to the palm, and the area of color change had decreased correspondingly. Ten weeks later the color phenomenon could still be elicited, but there was no remaining evidence of median nerve paralysis except anesthesia over the tips of the thumb, index and middle fingers.

Splenectomy for Purpura Hemorrhagica. — Eighty-one reported cases of splenectomy for thrombocytopenic purpura hemorrhagica are reviewed by Whipple, including four personal cases. He is convinced that this operation has contributed the greatest advance to the therapy of the purpuras, but it must be remembered that the favorable results are largely limited to the chronic variety. Furthermore, patients after splenectomy should be cautioned and guarded against infections, in order to obtain the best results

Nephritis in Pregnancy.—Many of the toxemias of pregnancy are associated with nephritis and can be classified as are other types of nephritis, not necessarily occurring in pregnancy The classification of Volhard and Fahr is followed by Rockwood et al The course of fifty-seven cases occurring during pregnancy is followed, together with the fate of the mother and child, over a period of three years Both nephritis and toxemia of pregnancy seem to be general diseases affecting the cardiorenal vascular system as a whole. When the toxemia of pregnancy is classified by the same method that Volhard uses for nephritis, a marked difference in the end-results is seen and this difference allows the physician to make a more accurate prognosis, both as to the mortality among the mothers and as to the fate of the child in subsequent pregnancies

Secondary Cancer of Umbilicus.—Besides reporting one case of cancer of the umbilicus secondary to adenocarcinoma of the cecum Head presents a clinical and pathologic summary of 101 instances of carcinoma of the umbilicus which have appeared in the literature

Varix of Superficial Epigastric Vein.—A varix of the superficial epigastric vein is reported by Hughson. The usual diagnostic signs were absent, possibly accounting for the erroneous clinical diagnosis of femoral hernia.

Antigenic Effect of Spermatozoa. — Fogelson's results confirm the work of others It is evident that there is an accurate method of temporarily inhibiting conception by sensitization of the female rat to any spermatozoa protein. This antigenic effect of spermatozoa is not specific for species, but equally good results can be obtained from the spermatozoa of any species The mechanism causing this sterility is still not clear

Acute Hemorrhagic Pancreatitis. — Butler and Delprat report an early case of acute hemorrhagic pancreatitis. As the pathologic changes were localized definitely to the tail of the pancreas, resection seemed the logical procedure The patient made a complete recovery.

Secondary Staphylococcus Meningitis.—The case reported by Moise showed a congenital sacral sinus with an underlying spina bifida and a direct connection between the skin and the spinal canal The occurrence in this case of a pilonidal sinus with an underlying spina bifida and an irregularity in the fusion of the sacral vertebrae is additional evidence in favor of the view that such sinuses are developmental anomalies resulting from a failure of the medullary canal to become completely obliterated. This lesion had given the patient no cause for worry until the eighteenth year of his life, when it served as the portal of entry for a meningeal infection. A sacral laminectomy with drainage was performed with subsequent recovery from the meningitis.

Hernia in Broad Ligament.—Dunn reports one case and gives a résumé of four cases recorded in the literature.

Partial Gastrectomy with Telescopic Anastomosis.—Instead of making an end-to-end junction of stomach and duodenum, Babcock turns the duodenum into the open end of the gastric mucous membrane and the outer end of the gastric stump after a high resection of the gastric mucous membrane and the outer serous surface of the duodenum is united to the inner surface of the denuded muscularis of the stomach The entire thickness of the cut end of the duodenum is united to the gastric mucosa The telescopic union is said to have the advantage of strength, reinforcement and mechanical adaptation. The depth of invagination is from 2 to 6 cm, and varies with the available length of the duodenal stump, and the amount of stomach resected

Anastomosis of Veins.—A method is described by Bird for anastomosing veins. No special instruments are necessary and the procedure may be carried out rapidly under direct vision with assurance of a successful outcome. A large, oval opening is provided

Venoclysis.—Venoclysis has been resorted to by Hendon in the following conditions: virulent pelvic infection of a tubo-ovarian abscess and plastic work on the cervix and vagina; intestinal paresis following delayed operation for obstruction; emesis gravidarum; uremia; ruptured bowel and virulent puerperal infection following operation. In each instance, the use of venoclysis was begun after the usual remedies had been tried and had failed and the patient's condition seemed hopeless; hence, the mortality was necessarily high, but not discouraging.

Use of Mercurochrome in Puerperal Infection.—Robinson concludes that, from all reports so far, it is not possible to state that mercurochrome-220 soluble is a specific cure for blood stream infections. Robinson reports five cases in which a 1 per cent solution of mercurochrome was injected intravenously in 20 cc. doses.

Chronic Abdominal Pain in Children.—Toverud points out that chronic constipation will in some children sooner or later give rise to a picture that may suggest a severe disease. Recurrent abdominal pain is the most predominant feature of this condition besides general malaise. The condition covers mostly what in different pediatric textbooks has been described under the name of "colitis," "chronic gastric catarrh" or "intestinal colic." In Toverud's experience the cause seems mostly to be poor food and the child's bad habits. A change in the food to the so-called constipation diet (much fruit, vegetables, lactic acid milk and whole meal bread) and a change in the child's habits have been able to cure these children completely.

Palpable Arterial Coats in Children.—Vipond reports cases of arterial thickening in children. This condition is a familial one, and nonsyphilitic in origin. This arterial thickening is found in very young children; in fact, it is a congenital condition, and these children enter this world with a thickening of the whole of the arterial system. This must not be confounded with arterial diseases caused by congenital syphilis. It is a familial condition, and most of the children in the family have thickened arterial coats. The thickened condition of the arterial walls can readily be detected, and the artery can be felt to roll under the finger. When examining these little patients, one must make very gentle pressure with the finger tips. Whenever a child is thin and below the normal size, Vipond says it is well to look for palpable arterial coats.

Obstruction of Intestine by Gallstones.—Bennett reports three cases without mortality. In one case, a stone 1 inch (2.5 cm.) in diameter, weighing 140 grains (9.5 Gm.) was impacted in the ileum, 20 inches (50 cm.) proximal to the ileocecal valve. In the second case, the stone was a truncated cone. The greatest length equaled the greatest breadth; namely, 1⅕ inches (3 cm.). The dry weight was 180 grains (12 Gm.). It was lodged in the ileum, 4 or 5 inches (10 or 12.5 cm.) proximal to the ileocecal valve. The stone removed from the ileum in the third case was ovoid in shape, the greatest circumference being 5½ inches (14 cm.) and the weight was 636 grains (42.5 Gm.)

Active Immunization Against Tuberculosis.—Raw's experience with active immunization of animals against a virulent dose of tubercle bacilli has been encouraging, and he hopes that in the near future the work will be extended to young children, with a view to protecting those who are in daily contact with cases of open tuberculosis.

Noninfective Arthritis in Women.—Cumberbatch and Robinson assert that there exist cases of arthritis occurring at either end of menstrual life which are not due to infection; that in some of these, at all events, the arthritis is due to deficiency of ovarian hormone, and that in these the arthritis and accompanying ill health are efficiently treated by heating the pelvic organs by means of diathermy.

Results of Insulin Treatment.—Of 100 patients with diabetes of all types treated by Thomson with insulin and dieting, seventy-five survive—sixty-one in good health and fourteen in poor or moderate health. Of the twenty-five deaths that occurred, one resulted from the treatment and ten others were not directly due to diabetes but may have been accelerated by it; in seventeen of the fatal cases there were definite complications. Of twenty-one patients with coma either actually treated in the stage of full unconsciousness or close to it, twelve recovered. Of the ten patients concerned, five remain in fairly good health; the others have since died. A type of persistent coma which Thomson believes particularly liable to occur in treatment by insulin is described. Recovery from this type of coma after intrathecal injection of insulin is recorded. The importance of early insulin treatment in young patients is emphasized. All patients who have kept a normal blood sugar and have remained free from glycosuria have done well; their condition at this time, however, does not appear materially better than that of those who have shown glycosuria at times but who nevertheless have managed to keep the early morning specimen free.

*Variation in Mortality from Cancer Among Persons in Different Districts of Glasgow and Its Relationship to Social Status. M. Young.—p. 205.

Sense of Smell.—Halliday asserts that the responses of odors may be considered as a form of chemotaxis; in man they remain primitive in type, and consist mainly of mass movements of attraction or repulsion. Smells have no intellectual value, as integration at the higher levels does not occur. Grouping of smells does not take place in the mind, as there is no abstraction of qualities common to a series of smells. The individuality and isolation of the responses to odors largely explain the infinite variety of smells. As no real mental grouping occurs, the construction of a spectrum of odors would appear to be a human impossibility; for a similar reason the theory that an art could be founded on odors is fallacious. As there is no abstraction of their qualities, symbolic formulation of smells cannot take place. The expression in speech of the conscious responses to odor is therefore limited, and there is a natural aphasia which corresponds to certain cases of acquired aphasia in which an anatomic lesion produces a dissolution of the higher levels of function.

Cardiopulmonary Syndrome in Rheumatism.—In the routine examination of cases of rheumatism Mavor has been impressed with the appearance of a certain group of signs over the base of the heart. This group is present in cases in which there is at least a presumption of rheumatic infection, and may or may not coincide with other cardiac manifestations. The signs are not susceptible of being recorded by instruments or corroborated and explained by postmortem examination. The phase of the disease at which they occur is seldom mortal. The signs are as follows: The cervical veins are visible and pulsating, and this is usually more obvious on the left side of the neck. The veins appear to collapse on ventricular systole. On very slightly forced inspiration they stand prominently. Pulsation is visible, or at least palpable in the second and third left interspaces. A faint diastolic shock is felt in this area. The resting pulse is rapid—about 100 per minute. Tachycardia, with some irregularity, appears on exertion. Percussion yields a relatively dull note from the first interspace to the base of the precordial dulness, and for an inch and a half or more to the left of the sternum. Over this area the respiratory murmur is bronchovesicular, and the bronchial sounds are audible horizontally for twice the distance over which they can be heard on the right side. A local cog-wheel rhythm is very common, and vocal fremitus, vocal resonance and whispered sounds are relatively increased. A peculiar bruit is heard in the neighborhood of the second left interspace close to the sternum. It begins at, or very shortly after, the closure of the first sound. It is loud, moderately pitched, and rather rasping, like the passage of a hard cloth-brush over silk. It runs crescendo up to an accentuated second sound, whose quality is like that of the rapping first sound in classic mitral stenosis. The bruit may, in some cases, begin as a soft blow masking the close of the first sound, but it always takes on a harsh quality as it gathers volume. Outside this area, a common pulmonary systolic murmur may be heard. The bruit does not necessarily vary with respiration, but if it does, it becomes first louder and then fainter on inspiration. Forced inspiration may abolish it. It is louder when the patient sits up or takes the knee-elbow position. It may disappear altogether for a period of days and may vary in intensity during a single examination. During its absence the second sound is often reduplicated.

Social Status and Cancer Mortality.—The medical officer of health for the city of Glasgow has hinted that cancer in Glasgow among the leisure classes is more than twice as prevalent as it is among the wage earners. Young, on the other hand, fails to find any evidence of coincidence between a relatively excessive mortality rate from cancer in the municipal wards of Glasgow and high social status of the residents therein, such as might be inferred from their crude mortality rates for this disease; indeed, the correlation coefficients that have been calculated appear to suggest that a definite tendency to the converse relationship exists.

*Meningitis Carcinomatosa. T. G. Moorhead and T. J. Wigham.—p. 135.

Meningitis Carcinomatosa.—The patient, whose case is reported by Moorhead and Wigham, complained of pain in his head, vomiting and breathlessness. He was extremely cyanosed. He presented the typical phenomena associated with meningitis. The diagnosis was serous meningitis, following influenza, or some similar infection. A postmortem examination was refused, but the brain and spinal cord were removed. Apart from the very slight thickening here and there of the pia mater, absolutely nothing abnormal could be detected. Microscopic sections disclosed a tumor growth of endothelial type covering over practically the entire cerebral cortex, and also the cerebellum. The growth was far too thin to be visible to the naked eye, except here and there as a slight opacity of the pia. In the spots in which the pia appeared most thickened, the tumor formation was extending into the brain, its most characteristic arrangement being a single row of cells surrounding vessels. In these areas also the brain occasionally showed necrosis, nothing but the vessels and tumor cells being left intact. This penetration was most plainly to be found in the cerebellum in which the cells were mostly in small solid columns with only slight tendency to the formation of a hollow tube. In a few places the cells formed larger masses; even then there was some slight tendency for the cells to lie in rows. Examination failed to reveal any definite tumor mass which might be the primary focus from which the rest was derived.

*Herpes Zoster Oticus and Allied Conditions. T. Guthrie.—p. 710.

Treatment of Ileus by Choline.—While engaged in an investigation of the rhythmic movements of the small intestine in 1912, Weiland made the chance observation that when a piece of isolated intestine was allowed to contract in Ringer's solution for some time the fluid acquired the property of exciting contraction in other pieces of intestine placed in it. Le Heux, another worker in Magnus' laboratory in Utrecht, isolated the substance causing this effect and identified it as choline. This base is related chemically to muscarine, the principle found in poisonous mushrooms. Wolf and Canney report three cases of ileus in which choline appeared definitely to restore muscular tone and contraction in the intestinal wall, in one of the cases, after all other remedies had failed over the space of three days. The administration of choline is a simple matter. Sterile choline hydrochloride is put up in glass ampules containing 600 mg. in 6 cc. This solution is diluted with 180 cc. of sterile physiologic sodium chloride solution, and the resulting solution is injected intravenously. An important point in administration is that it should take at least seventeen minutes to inject the whole quantity.

Scarlet Fever Antitoxin in Convalescent's Blood.—If the unit of antitoxin is taken as that amount which gives complete neutralization of one skin test dose, then out of twenty scarlet fever children, seventeen were found by Henry and Lewis to yield a serum which contained 50 units or more of antitoxin, whereas of the nonscarlet fever children only eight reached this titer. Of the twenty children with scarlet fever, nine yielded a serum containing 125 units or more, whereas only three of the children not having scarlet fever did so. The 250 unit level was reached by five scarlet fever children and by one nonscarlet fever child.

Herpes Zoster Oticus.—Three cases are reported by Guthrie, the first two being characteristic examples of herpes zoster oticus, and the third a case of herpes facialis with eighth nerve symptoms.

Fever Resembling Typhus.—A fever of about twelve or fourteen days' duration, characterized by severe headache and a macular rash on the body and limbs, is described by Wheatland. The fever is believed to be identical with that described by Hone in Adelaide. It is not contagious. It is probably transmitted by some ectoparasite associated with the mouse. Wheatland suggests the existence of a group of diseases resembling typhus fever of which this fever is a member.

Serologic Test for Gastric Cancer.—Roccavilla thinks that Salomon's test can be dependable if an extremely potent immune serum is used for the test. He found the response constantly negative in five subjects with normal stomachs, and positive in eight of ten with cancer of the stomach. The exceptionally potent anticancer immune serum was obtained from rabbits prepared by repeated injections of an emulsion of resected gastric cancer tissue; the controls by injections of simple fasting gastric juice. The reaction allowed identification of the patient's endogastric proteins, revealing or excluding malignant disease with nearly 90 per cent accuracy.

*Rôle of Infection in Peptic Ulcer. P. Duval et al.—p. 3.

Infection in Gastric and Duodenal Ulcer.—This entire issue is devoted to research on the share of infection in the evolution of gastric and duodenal ulcers. Duval and his co-workers describe how infection modifies the clinical symptoms and the histologic and biologic findings even of perforated ulcer. No operation should be attempted during an acute phase of infection or before the abnormal biologic reactions have disappeared. To prepare the patient for the operation is thus the main thing. Bed rest, preoperative vaccination, and operating in sound tissues improve the prognosis.

16: 153-272 (Feb.) 1926

*Tetany of Gastric Origin. R. Grégoire.—p. 153.
Colectomy. A. G. Weiss.—p. 169.
Phenoluria and Urobilinuria. E. Binet and A. M. de Fossey.—p. 226.

Surgery in Tetany of Gastric Origin.—Grégoire discusses the explanation of tetany associated with gastric disturbances. Obstruction of the pylorus and subsequent repeated vomiting entail a reduction of hydrochloric acid in the organism, and thus induce physical and chemical changes in the blood serum. This causes irritation of the nervous system and tetany. When symptoms denote an impending attack of tetanic spasms, it may be averted by injections of from 800 to 1,000 Gm. of physiologic salt solution, with or without addition of 10 Gm. of sodium bicarbonate. This combats the dehydration. The next step is to remove the obstacle in the pylorus. Gastro-enterostomy is sufficient in most cases; otherwise, it has to be completed by a more radical operation later. While with expectant treatment the death rate has averaged 80 per cent, after operative treatment it dropped to 37 per cent.

The Erythredema of Young Children. J. Comby.—p. 105.

Hypertrophy of the Heart in Infants.—Mouriquand, Bertoye and Charleux describe a case of hypertrophy of the heart in an infant, aged 13 months. The hypertrophy was associated with grave anemia. The systolic murmur heard in the precordial region was so intense as to suggest interventricular communication. Necropsy showed the interventricular septum intact, with coexisting hypertrophy of the kidneys. The latter as well as the heart appeared histologically sound. Thus the murmurs were merely of inorganic origin. The rarity of these murmurs in infants is explained by the relatively weak contractions of the myocardium at that age.

Dumbness Accompanying Typhoid in Children.—Debbas has observed within a year four cases of dumbness in the course of typhoid, in children, aged from 3 to 7. In one instance it persisted for ten days; in three for a month. In none of these cases was there any meningeal reaction.

The Dick Test in Measles. J. Paraf.—p. 506.

The Dick Test.—Lesné and Dreyfus-Sée relate that pseudoreactions were avoided when using Zoeller's toxin (purified by acetic acid and sodium chloride). They applied this toxin in seventeen children, aged from 2 to 13, without any scarlet fever history. In eleven the Dick test was positive; it was negative in six, thus testifying to a spontaneous immunity. In a group of twenty-one with scarlet fever, the reaction was positive in seven and negative in five by the third to the seventh day. Of fifteen convalescent children, the Dick test was negative in twelve; positive in three on the twenty-sixth to thirty-fourth day. The test was also negative in a child who had had scarlet fever several years before. Their conclusion is that the Dick test cannot be applied in diagnosis of scarlet fever, present or past. Neither does it testify unerringly as to the receptivity or immunity of a subject, or prove the streptococcus toxin theory as to the cause of the disease.

Septicemia with Recovery After Fixation Abscess.—Villaret and his co-workers observed multiple manifestations of staphylococcus septicemia in a tuberculous young man. The usual drug treatment as well as vaccines were without avail for five months, until finally an abscess developed spontaneously on the right thigh. It was incised and the general condition improved and no local or general signs of the staphylococcus infection have reappeared during the four months since. The simultaneous improvement of the tuberculous lesions in the lung may be ascribed, they think, to humoral changes and increased leukocytosis induced by this spontaneous fixation abscess.

The Dick Test from Standpoint of Immunity to Scarlet Fever.—Debré, Lamy and Bonnet have applied the Dick test in 677 children. The reaction was positive in 25 per cent under 1 year; in 44 per cent from 1 to 3 years, gradually dropping to 15 per cent at the age of 15. The proportion of positive reactions in 122 adults was 10 per cent. At the onset of scarlet fever the Dick test was positive in eight of nineteen children; negative in ten, and a pseudoreaction was noted in one. In all of sixty-four convalescent children, the reaction was negative. In four cases of scarlet fever a positive Dick test had been recorded a few weeks or months before. The reaction became negative in all in the course of convalescence. In ten instances a mild form of scarlet fever appeared within forty-eight hours after one or repeated injections of streptococcus toxin. They query whether this was a mere coincidence, or whether a minimal dose of toxin had induced phenomena of sensitization in bacilli carriers. The extinction of a positive Dick test by a mixture of toxin and serum paralleled always the blanching of the scarlet fever eruption in the Schultz-Charlton test. The intradermal reaction was applied in ten cases of different streptococcus affections; in nine it was negative; a pseudoreaction appeared in the tenth. They conclude that the Dick test cannot help in diagnosis of scarlet fever; but it may reveal whether or not there is immunity to the disease, and indicate the proper serum for prophylaxis or treatment of scarlet fever.

Changes in Cerebrospinal Fluid in Serum Sickness.—De Lavergne and Abel examined the cerebrospinal fluid of twenty children and adults with serum sickness, especially with generalized urticaria, after one or repeated injections of an antiserum. There was an increase of sugar, and lymphocytosis; the amount of albumin remained normal. Coexistence in these cases of headache, nausea and vomiting suggests a possible meningeal reaction, responsible for the changes in the cerebrospinal fluid. Meningeal reactions and subsequent radiculitis may explain certain paralyses following injections of serum.

Phenol Autointoxication and Diuresis.—Binet, Mathieu de Fossey and Goiffon noted an exaggerated content of phenol in the urine in seven of eleven cases of colitis, and in six of eight cases of obesity, diabetes, gout or overeating. High phenoluria was manifest only in two of nine cases of constipation, without colon disturbances. There was pronounced phenoluria in ten out of eleven cases with associated lesions of the cecum, colon or gallbladder. This was always accompanied by an excessive urobilinuria. In twenty of twenty-five cases of phenoluria, the diuresis was increased; in the others there was only 1 liter of urine or even less, in twenty-four hours. Phenomena of auto-intoxication existed only in the latter. It thus appears that not only the liver neutralizes a part of the phenols from intestinal putrefactions, but there is also an elimination by way of the kidneys, a compensatory diuresis.

6: 469-502, 1925

*The Neuroglia and the Third Element in the Nerve Centers. P. del Rio Hortega.—p. 469.

The Third Element in the Nerve Centers.—Del Rio Hortega's fine photomicrograms sustain his assertions in regard to the third element in the nerve centers, which he calls provisionally the microglia. It is always more abundant in gray matter than in white, and seems to occur identically in all vertebrates. It migrates to points where it is needed, and hypertrophies, adapting itself to local space conditions, and phagocyting the waste products of nerve tissue. In these various phases it has been called by different names, and conflicting theories have been based on it. He regards its scavenger function as part of its general task to keep away from contact with the neuron everything that might hamper the exalted function of the latter.

Electromyograms and Muscle Fatigue.—Laubry, Walser and Deglaude isolated the gastrocnemius muscle of a frog (with intact nerve and vessels) and exposed it to the faradic current. The recorded electromyograms resembled the electrocardiograms usually attributed to block of branches of the bundle of His. Of course no conduction apparatus could be involved in these muscle experiments. It is possible that the changes revealed by the electrograms are in both instances of muscular origin; namely, due to muscle fatigue.

The Invisible Forms of Visible Bacteria.—Hauduroy found abnormal forms of bacteria in polluted well waters, which he isolated by filtration. Further research demonstrated different stages of these bacteria. First the bacteria are invisible; then they acquire a granular form; and finally change to the form by which they are known now.

The Cholesterogenous Property of the Spleen.—Abelous and Soula severed the crural and sciatic nerves in chloralosed dogs, and then excluded the spleen from the general circulation. After the peripheral ends of the nerves had been faradized for five minutes, blood was withdrawn from the femoral artery and vein. There was less cholesterol in the venous blood than in the arterial, while there was more cholesterol in the vein than in the artery after the circulation had been restored in the spleen. This seems to confirm that the internal secretion of the spleen increases the amount of cholesterol.

Hemolysis and Amino-Acids.—Loeper, Decourt, Olivier and Lesure conclude from their research that hemolysis is one source of amino-acid formation as well as of formation of the bile pigment. A part of the amino-acids may be produced by hemolysis occurring in the spleen itself.

Parallelism of Thyroid and Pancreas Development.—Aron observed that the appearance of colloid secretion in the thyroid coincided with that of Langerhans' islands in the pancreas. Both organs develop very early in the cow fetus; in the pig fetus, only during the last weeks of intra-uterine life; in the guinea-pig fetus during the last days. The functional characters of the thyroid and pancreas are definitely established simultaneously in the human fetus, at the end of the third month of pregnancy.

Hypercholesteremia and Naphthalene Cataract.—Rabbits were fed a mixture of glycerin and naphthalene. Lesions of the retina appeared by the twelfth to twentieth day, followed by bilateral cataract. The eye phenomena were preceded by a two or threefold amount of cholesterol in the blood. The theory is that disturbances of the suprarenal secretion may induce cholesteremia and the eye lesions. Michail and Vancea emphasize the analogy between the hypercholesteremia from naphthalene and the hypercholesteremia with senile cataract. With congenital or juvenile cataract, the cholesterol content of the blood is normal. It is possible that deranged functioning of the suprarenals may be a factor in senile cataract, and deranged functioning of the thyroid and parathyroids a factor in congenital or juvenile cataract.

*Tumors of the Frontal Lobe. P. Escuder Núñez.—p. 37.
True Paranoia. H. Claude and M. Montassut.—p. 57.
*Pupil Immobility with Alopecia Areata. E. Herman.—p. 64.

Tumors of the Frontal Lobe.—Escuder Núñez reviews the clinical syndrome of tumors of the frontal lobe as observed in two personal cases and in sixteen recorded observations. Unilateral loss of the sense of smell, choked disk, deviation of the head and feet to the opposite side, or paralysis of the movements of the head and eyes to the opposite side are the sensory and motor symptoms. The psychic symptoms from excitation include hyperexcitability of the imagination, and moral insanity; from inhibition, somnolency and partial stupor, with or without other general symptoms of a brain tumor, headache, vomiting, dizziness, intraspinal hypertension, etc. A two-stage operation seems to be preferable to a single sitting. The first stage of decompression is often followed by improvement, and sometimes by survival for several years. Béclère and Nordentoft have reported remarkable results from radiotherapy, combined or not with an operation. He has had no personal experience in this field.

Alopecia Areata of Sympathetic and Endocrine Origin.—Herman reports a case of alopecia areata in a girl, aged 14. The affection, starting three years before after a severe fright, was accompanied by epileptic seizures. It induced loss of hair of the head and body as well as of the eyebrows and lashes. Clinical examination revealed general debility, insufficiency of the ovary and pituitary, possibly also of the thyroid gland. Besides the endocrine disturbances, there were phenomena of *sympathicotonia*, including spontaneous dilatation of the pupils and transient immobility to light. This may have been caused by excessive irritability of the sympathetic system and consecutive spasm of the dilator of the *iris*.

*Bulbar Syndrome. G. Marinesco and S. Draganesco.—p. 89.
*General Paralysis. Sézary and Barbé.—p. 99. Begun. p. 1.
Malaria Treatment of General Paresis. Nicole and Steel.—p. 116.
Brain Tumor with Psychasthenic Syndrome. Marchand and Schiff.—p. 121.

Syndrome from Interolivary Region.—The syndrome was observed by Marinesco and Draganesco in a previously healthy man, aged 55. The disease had commenced ten years before with paresis of one side of the body, five years later involving the other side. Finally bulbar disturbances appeared, such as difficulty in swallowing, and in the use of the tongue, sometimes aphonia. The case was considered a form of amyotrophic sclerosis or atypical syringomyelia. The necropsy findings showed atherosclerosis of the spinal cord, pons and medulla, especially of the region between the olivary bodies. The large patch of necrosis in the latter region explains the paralysis of all the limbs. Coexistence of intraneuraxial neuromas, as well as the incomplete development of the medulla and spinal cord suggest a possible congenital origin of the disease. The six somewhat similar cases on record all ran a rapid course.

Drugs in Treatment of General Paralysis.—Sézary and Barbé compare the action of different drugs in eighty-eight cases of general paralysis. They conclude that arsenicals are most effectual, while they influence favorably the mental condition of the patients. The quinquivalent are usually superior to the trivalent. Bismuth has no action on the mental condition but, owing to its biologic action, especially on the leukocytosis of the cerebrospinal fluid, it may be used as an adjuvant in treatment of general paresis.

Strangulated Obturator Hernia. P. Bonnet.—p. 44.
*Ramisection. R. Leriche.—p. 60.
Flexner's Book "Medical Education." A. Policard.—p. 65.

The Normal Gastric Secretion.—Dahl-Iversen's experiments were made with thirteen young men and two young women—all healthy—and he tabulates the findings separately for each one for a week. An hour after an oatmeal gruel meal, with phenolphthalein for the indicator, the figure averaged 47, while with bromin-cresol-purple as the indicator, the figure was 41. With the Ewald test meal, the phenolphthalein figure was 54. He was astonished at the wide variations in the findings in different persons and at different times in the same person under apparently identical conditions. No influence from tobacco was apparent.

Ramisection.—Leriche has severed the rami communicantes in the neck in eighteen cases. The operation does not modify the sensations of contact, cold, heat and pain but it alters that mysterious internal sense of the reality of the existence of our body. He describes one case in which a man with an extremely painful amputation stump, and hallucination of painful contracture in the fingers of the missing hand, was freed from all his pains and hallucinations by ramisection from the second cervical to the first dorsal rami. Such cases suggest a new field for surgical treatment of painful and perverted cenesthesia, that is, the sense of conscious existence, of normal functioning of the organs of the body. The rami communicantes seem to be the vehicle for transmission of the cenesthesia stimuli.

Various Technics for Blood Transfusion. A. Tzanck.—p. 301.
Forms of Pneumobacillus Sore Throat. J. Chalier et al.—p. 305.

Flaring Up of Tuberculosis of the Lung After Operations Elsewhere.—Bezançon and Jacquelin report seven cases in which an operation for nontuberculous affections as, for instance, appendicitis or hernia, was followed by development of tuberculosis in the lung. In four instances this occurred after ether; in three after chloroform. They never observed it after nitrous oxide or any local anesthetic. The skin test was applied in eighty-six cases after operation. It was negative in 40 per cent after ether; in 25 per cent after chloroform, and only in 7 per cent after intraspinal anesthesia. The fact confirms the toxic action of ether and chloroform on the liver; the postoperative anergy appearing as a form of liver anergy. Therefore in patients with suspected or a developing tuberculosis, an operation should be made preferably under local or intraspinal or even nitrous oxide anesthesia.

Treatment of Typhoid Fever. A. LeSage.—p. 35.

Use of Scarlet Fever Antiserum in Montreal Hospitals.—Seventy-five nurses of the Alexandra Hospital entering the contagious disease service were given an immunizing dose of scarlet fever antiserum. About 9 per cent of them developed a mild form of the disease three weeks later. The preceding experience had been, before this attempt, that 15 per cent of all the nurses contracted grave scarlet fever during their service. It appears that the immunization from the scarlet fever antiserum does not last more than three weeks. A total of 125 scarlet fever patients have been treated with concentrated antiserum in the last six months. A dose of 5 cc. was injected intramuscularly in benign cases; 10 cc. by the vein in grave cases. There was no fatal outcome among those thus treated. In 200 patients of the Alexandra and St. Paul Hospitals, treated with this serum, the common complications of scarlet fever occurred more rarely, and they were always mild. No symptoms of serum sickness were noted after the concentrated serum was employed. The effect seems to be like that observed in diphtheria with antitoxin treatment.

*Habitual Epistaxis. Gallusser.—p. 250.
*Heart in Exophthalmic Goiter. G. Bickel and E. Frommel.—p. 251.
Iodin in Proprietary Preparations. Hunziker.—p. 257.

Technic for Filling Cavity in the Lung.—Josefson has devised a combination of syringe and spatula to facilitate injection of contrast and therapeutic substances into the lungs.

Scleroderma and Roentgen-Ray Castration.—Schwarz' patient—a woman constitutionally substandard—developed scleroderma after sterilization by roentgen rays at the age of 40.

Fat Embolism.—Weingarten's study of 100 necropsies revealed no endogenous cause for the fat embolism—especially no nephritis. Slight traumas may be easily overlooked. Injections of camphorated oil may cause considerable accumulation of oil in the pulmonary capillaries.

Habitual Epistaxis.—Gallusser recommends submucous resection of the septum in habitual nosebleed and with a perforating ulcer of the septum.

The Heart in Exophthalmic Goiter.—Bickel and Frommel declare the prognosis in cardiac disturbances in exophthalmic goiter at the same time is infinitely better and infinitely worse than in heart disease of other origin. The prognosis is more favorable because severe arrhythmia and weakness may be followed by complete recovery, and the prognosis is graver because sudden death may occur with apparently slight changes of the heart.

*Retrogression of Tumor Under Organotherapy. J. Bacalhau.—p. 371.

Thyroid Treatment of a Mediastinal Tumor.—Bacalhau urges physicians to cooperate in studying the effect of organotherapy on tumors, as few hospitals are able to keep a patient long enough to determine the ultimate outcome. His success in a case described justifies, he says, extensive application of this method of treatment. His patient was a robust working man, aged 54, who in 1923 began to have dyspnea on exertion; cough and hoarseness soon followed, with progressive attacks of suffocation. The symptoms and radiologic findings indicated a tumor in the mediastinum and its growth upward threatened suffocation. The clinical course indicated a benign character, probably a lipoma, but its extension forbade operative intervention. No benefit was realized with treatment for syphilis—the Wassermann test was weakly positive—but Naamé's recent report of the retrogression of two malignant tumors under organotherapy encouraged its application in this case on the assumption of endocrine disturbance and the influence of the thyroid on the metabolism of fat. A testicle extract was given with the thyroid extract, and in five days there was considerable relief, allowing the patient some sleep at night. The tumor continued to retrogress and the man was discharged from the hospital in six weeks, with slight dyspnea on exertion as his only complaint. He takes the tablets only occasionally now, and has resumed his former occupation.

Spasm in the Gastro-Intestinal Tract.—Steindl found degenerative changes in the medulla and pons, localized especially near the dorsal nucleus of the vagus, in four cases of intestinal spasms (spastic ileus in two of them). Calcium helps in such cases if administered in large doses. Paravertebral anesthesia produces a predominance of the vagus by inhibition of the splanchnic nerve and is therefore not advisable for spastic conditions in abdominal organs.

Internal Fistulas.—Clairmont interposes a well nourished pedunculated flap of subcutaneous fat from the thigh in treatment of vesicorectal or vesicovaginal fistulas.

Postoperative Albuminuria.—Schulze observed transitory albuminuria practically always, together with acetonuria, after surgical interventions made under ether or local anesthesia. He never saw it after intraspinal anesthesia.

Serum Proteins in Test Diuresis.—Lasch determined the fractions of serum proteins in diuresis tests. With good elimination, the total protein level of the serum rose; the globulin fraction declined. With deficient diuresis, either the total protein decreased while the globulins increased, or vice versa.

Homoioplasty of Skin.—Gohrbandt obtained successful transplantations of skin only in young rats of the same litter. He failed in 150 attempts in other animals. Parabiosis did not improve the results.

Ileus and Drop in Blood Sugar.—Kubányi found moderate hypoglycemia in some of his dogs with experimental ileus.

Physicians in Germany, 1925. Prinzing.—p. 498.

Antagonism and Synergism.—Führer, who as long ago as 1907 regarded tetany as guanidine poisoning, deals with various synergists and antagonists. Calcium is a true antagonist, barium a true synergist of guanidine. Strontium is its synergist in regard to the increased tonus, its antagonist by suppressing the rapid contractions of striped muscles. Dextrose and epinephrine are antagonists of guanidine. Combinations of different drugs may enhance one of the actions and suppress another—for instance, in a combination of amidopyrine with a barbital compound the narcotic action of both disappears while the analgesic effect becomes stronger. Bürgi's rule is evidently not universal.

Syphilis of the Pharynx and Mouth.—Plaut finds that a sudden beginning of the sore throat as well as the absence of fever speak against syphilis. A dental treatment received several weeks before may be an important item in the history of a primary lesion in the mouth. Not only tertiary but also secondary syphilis may cause an ulcerative membranous tonsillitis. He observed such a case in an elderly physician with a supposed panaritium, which was the primary lesion. Before the diagnosis was made, a son of the patient was infected by a kiss. Fusospirillar symbiosis in otitis media is frequently conditioned by syphilis. Absence of swelling of lymph nodes testifies against syphilis. Absence of fusiform bacilli and of spirochetes with a clinical picture of the Plaut-Vincent angina makes the diagnosis of tertiary syphilis probable.

Pernicious Anemia.—Kairiukschtis injected rabbits with an emulsion of bone marrow obtained at necropsies of pernicious anemia patients. The rabbits died under grave local and general symptoms. He believes that he found megaloblasts in the blood of some of them. His controls were all practically negative.

Amebic Dysentery. W. H. Lamberts.—p. 513.
Vocational Guidance. K. Brockmann-Rohne.—p. 517.

Seasickness and the Sense of Balance.—Abels analyzes the pathogenesis of seasickness. The unaccustomed tactile and kinesthetic stimuli, and especially those originating in the vestibular apparatus, are responsible. The novel nature, the long duration and the exogenous origin of these stimuli are of importance. The phenomena of seasickness are aggravated by any effort to perform complicated movements. Persons who have become immune to seasickness on one boat may get seasick on a boat of different construction.

Lactacidemia in Cancer.—Schumacher found an increased lactic acid concentration in the blood (22-34 mg. per hundred cubic centimeters) of those carcinoma patients who had metastases in the liver. The other patients had normal amounts (9-15 mg.).

Spirochetoses.—Steiner and Steinfeld obtained superinfections in animals that had been mildly infected with recurrent fever. Later on, it proved possible to cultivate reinjected spirochetes from the blood without any other signs of reinfection becoming manifest. The immunity may be increased for a few weeks by reinjection of virulent material.

Starvation Treatment for Epilepsy.—Karger had only a few fair results in treatment of epilepsy in children by starvation. He would reserve this treatment exclusively for cases of impending status epilepticus. An acidotic diet (meat, cream, eggs) was also effectual in a few instances. When he added a little sugar to the water allowed to the fasting children, the acetonuria disappeared and the seizures returned.

Etiology of Nevus.—Meirowsky surveys the evidence of the idiotypical conditioning of nevi.

Cholesterol and Growth of Hair.—Jaffé accelerated the growth of hair in rabbits by local application of ointments containing cholesterol. He explains the similar results obtained with tar by its action on the sebaceous glands. Administration of cholesterol by the mouth produced no results.

Liver Function Test.—A communication from the Merck establishment points out that only phenoltetrachlorphthalein (or its sodium salt) is suitable for the liver function test made by estimation of its disappearance from the serum. Tetrachlorphenolphthalein has not a sufficiently deep color.

Necrosis of Jaw After Occupational Benzene Poisoning.—Löwy's patient died of sepsis following necrosis of the upper jaw. He had been working in a tire factory with benzene and other material. Leukopenia with relative lymphocytosis and anemia were present. An acute benzene poisoning causes fever and a leukocytosis with prevalence of polymorphonuclears.

Sclerosis of Portal Vein.—Lehmann reports the history of a case of two years' duration. Symptoms of Banti disease with repeated hematemesis speak for a sclerosis of the portal vein. No urobilin was found in the urine of the patient.

Rupture of the Cardia by a Dilator.—After having had perfect results with Starck's method of brusque dilation of the cardia in seven cases, Maydl reports a death due to rupture of the cardia during the procedure. The force applied in this patient had been less than in some of the successful cases.

Typhoid Bacilli Carriers.—Bersch removed the gallbladder containing calculi in five typhoid bacilli carriers. No elimination of typhoid bacilli has been observed since.

*Protection of Infants and Mothers in Russia. A. Dworetzky.—p. 463.

Influencing the Soil in Infections.—Finkelstein shows that successful attempts to influence infections by modifying the tissues by the diet were made long ago by pediatricians. A diet poor in salt dries the secretion in weeping eczema.

Overburdening of School Children.—Junge pleads against overburdening the children in the schools. No physician is ever asked for his advice when a change of curriculum is contemplated. Each branch of instruction tries to increase the allotted time. Recently the music teachers succeeded in forcing singing lessons on preparatory school (gymnasium) students who are as old as Leibniz was at the time of his refusal of a position as professor. And attendance at the singing lessons is compulsory, without regard to the students' musical inclinations.

Protection of Infants and Mothers in Russia.—According to Dworetzky, the new organization of the welfare work for infants and mothers has reduced infant mortality to one half the previous figure. In the Moscow province it was as high as 27.6 per cent in 1913, and was only 13.7 per cent in 1923 in infants under one year of age.

Cancer in Mouth. H. Pichler.—p. 307.
Nervous Diseases of the Stomach. L. Hess. Supplement.—pp. 1-20.

Calmette's Vaccination.—Löwenstein criticizes Calmette's method. The immunity the latter claims to have obtained was limited to administration of virulent tubercle bacilli by mouth, not by injection. Yet many of even these animals died of tuberculosis, and there was no evidence as to whether the germs contained in their tubercles were due to the vaccination or to reinfection. A germ which is not virulent for guinea-pigs may be gravely pathogenic for man. Löwenstein had demonstrated that infection of guinea-pigs by feeding with virulent tubercle bacilli requires six months to two years to develop. Therefore the preliminary good results in children are not convincing. The virulence of the ingested germs may increase, especially in the young.

Contagiousness of Erysipelas.—Redlich and Krasso report several instances of infection of other patients from erysipelas patients transferred to the internal clinic. They consider complete isolation necessary.

Effect of Hysterectomy and of the Artificial Menopause.—Kraul investigated the disturbances in 252 cases of removal of the uterus and ovary or roentgen sterilization. The extirpation of the uterus alone caused no symptoms of Aschner's "dyscrasia," especially no hypertension. Extirpation of the adnexa or roentgen sterilization caused graver disturbances than the natural menopause. Transitory hypertension is often associated with myoma.

"Surgically Incurable" Gastric Ulcer.—Finsterer objects to this term. He found that recurrences of jejunal ulcers are due to the Y shape of the anastomosis and to insufficient resection of the stomach. A good resection should remove the whole lesser curvature and the larger part of the greater curvature. This means removal of two-thirds of a normal stomach, and more of a dilated organ. The alleged jejunal ulcers with anacidity would disappear from the reports if the gastric secretion were examined two hours after a regular meal, instead of twenty minutes after the Ewald meal.

Pulsation of Abdominal Aorta.—Pick confirms the probability of functional disturbances with strong pulsation of the abdominal aorta. The continual irritation of its surroundings may cause gastric distress, simulating an ulcer.

Angina Pectoris.—Braun reviews critically the history of the syndrome. It is a remarkable fact that Edward Jenner was the first to point to a sclerosis of the coronary arteries, and refrained from publishing his observation from consideration for John Hunter who had just presented the first signs of angina pectoris. The pain is of a peculiar nature; no matter how great any other pain may be—as for instance in trigeminal neuralgia—it always remains outside of the mind. It never breaks into the innermost personality of the sufferer, as true angina pectoris does. The patient may try to control any other pain: he may cry or scream, but he has not the feeling of being completely overcome—absolutely passive—such as the patient experiences during the attack of angina pectoris. The latter is actually an uncanny sensation of impending dissolution. This distress is the most important feature of the attack, and may be the only one. Attacks occurring without any pain are especially dangerous. A neurotic person may describe the distress; a sufferer from angina pectoris lives it. If the neurotic begins to suffer from real angina pectoris, he drops the theatrical description and presents his report with restraint and dignity. At necropsy in his 127 cases, the lumen of the left coronary artery was always found more or less obliterated.

Best Time for Cataract Operation.—Sachs deals with the question when to operate for cataracts. The intervention is never urgent, and therefore a good preparation for it is possible. Any conjunctivitis endangers the outcome. The lacrimal apparatus must be taken care of—eventually by extirpation of the sac. Cough from a catarrhal affection of the respiratory tract may rupture the wound. Codein is advisable in the catarrh of smokers. The "expulsive hemorrhage" sometimes following the opening of the eyeball in arteriosclerotic subjects with hypertension, may be prevented by bromides and copious venesection. Maturity of the cataract is not essential for its removal. The indication for it is given rather by the condition of the other eye. If the latter is good, the patient can wait till the cataract is ripe. Conservative treatment—except with diabetic cataract—has always failed so far. Römer had tried in 1906 a preparation obtained from animals' lenses, and later withdrew his originally optimistic claims. Another similar method ("phacolysis") has been recommended in recent years but the alleged favorable results were not confirmed at Dimmer's clinic. The reason for the alleged success is the slowness of the process. In 95 per cent of the patients the beginning cataract remains almost stationary for years. No wonder then that arrest of the process in 95 per cent of the cases is claimed.

Immunity and Allergy in Syphilis. H. Planner. Supplement, pp. 1-20.

Pathogenesis and Treatment of Myopia.—Müller started by investigating the reason why myopia starts usually after the ninth year and ends after the twenty-first. He found thirteen years ago by examination of 350 boys that the divergence of the visual axes is not a sequel of myopia. Quite the contrary, the myopes are recruited from the children with this divergence. He also concluded at that time that this is due to traction by the oblique muscle, not to a predominance of the external over the internal rectus muscle. He came to the conclusion that the elongation of the axis of the eye is not the primary lesion, but that it is produced by some processes connected with the growth of the orbit and the function of the oblique muscles of the eye. If the elastic band connecting the trochlea with the insertion of the obliquus superior, and serving also as a check band for the inferior muscle, is stretched by convergence of the eyeballs, the sclerotic is stretched and gets thinner exactly in the places typical for myopia. He severed the obliquus muscle in twenty-five eyes of twenty-one patients with grave myopia. The motor loss from the operation is negligible. The eyeball sinks about 3 mm. deeper. The myopia improved by 3-6 diopters. The changes in the choroid and retina retrogressed, the central visual acuity increased considerably. He has reason to assume that the operation may prevent detachment of the retina, and that it is essential for a cure. He intends to loosen the trochlear cartilage in children with beginning myopia. A retroposition of this kind would be a minimal intervention, and the possible benefit is great.

Caronia's Cultures.—Takaki was unable to confirm any of Caronia's claims. The alleged micro-organisms are probably a result of autolytic processes of the added pieces of organs. They gave nonspecific results when used as antigens in complement fixation tests with scarlet fever and measles convalescent serum. As to the protective value, he points to Hektoen's experiments which demonstrated the infectiosity of minimal amounts of blood taken from measles patients. The amount of original blood present in the cultures might be sufficient to immunize.

The Goiter Question.—Mezö grafted a piece of parenchymatous goiter from a boy with hyperthyroid symptoms under the oblique muscle of a girl suffering from dyspnea due to a large goiter. The goiter disappeared within four weeks.

Treatment of Obesity.—Bayor confirms Eppinger's results in treatment of obesity with novasurol. Short (seven) hours of sleep, exercises and dieting are also necessary. The salt intake should be restricted during the treatment.

*Abortion in Uterus Septus. R. Falk.—p. 673.
Theory to Explain Menstruation. R. Grósz.—p. 676.
A Calculus in the Ovary. H. Jentter.—p. 678.
"Clips in Suture of Perineum." P. Siiin.—p. 682.

Vaginal Reaction in the New-Born.—Kienlin found lactic acid in the vagina of new-born girls before any bacteria had time to develop. He concludes that it originates probably by fermentative action of the tissue itself.

Blood Requirement of Ovarian Cystoma.—Engelbrecht removed a carcinomatous cystoma, weighing 14 pounds, which had rapidly grown in four weeks. The fluid expressed from it contained enough iron to correspond to 5,600 cc. of blood.

Abortion in Uterus Septus.—Falk made with apparent success an artificial abortion in the second month of pregnancy in a woman with grave heart disease. She returned three months later with the uterus corresponding to the fifth month of pregnancy. This was due to another ovum situated in the other half of a double uterus with single cervix.

Nederlandsch Tijdschrift v. Geneeskunde, Amsterdam

1: 741-832 (Feb. 20) 1926

*The Netherlands Pharmacopeia. *H. Pinkhof.*—p. 742.
*Radium Treatment of Cancer of the Esophagus. W. F. *Wassink.—p. 746.*
*Swine Erysipelas Pathogenic for Man. C. Postma.—p. 754.
*Air Embolism with Criminal Abortion. J. P. L. Hulst.—p. 759.
A Spontaneous Hematoma in Abdominal Wall. P. Broertjes.—p. 768.

The Netherlands Pharmacopeia.—The fifth edition is now in press. Among the sixty-three new articles listed are glycerol suppositories, folia colei, crystallized strophanthin, and cinchophen. Among the same number dropped are croton oil and unguentum hydrargyri fortius. Pinkhof lists a number which should be dropped, and protests against the dropping of malaga wine. On account of the variable composition or proprietary ownership, ichthyol and arsphenamine are omitted, and the only organ extract given is thyroid.

Radium Treatment of Cancer of the Esophagus.—Wassink remarks that we can always be certain that conditions are worse than they appear to be in cancer of the esophagus. In nineteen of his forty-one cases the outlook seemed to be favorable, but all have died since except two; one of these, a man aged 67, is in excellent health two years and a half since the radium treatment. He had noted the first symptoms about six months before treatment was begun. Even merely palliative radium treatment long postpones a gastric fistula.

Swine Erysipelas in Man.—Postma cites Praussnitz' recent case in which a child, aged 10, died from chronic septicemia which responded to tests for swine erysipelas. This disease occurs in other domestic animals and in poultry, and it is possible that certain cases of chronic arthritis in man may be due to the same bacillus. It should be sought during the acute phase of joint disease. Edel urges search for it in cases of enteritis during an epizootic. In 164 cases of swine erysipelas in a light form, Postma found the bacilli in the meat in 66 per cent, but they were all killed by heat; pieces of meat weighing 800-1,800 Gm., and 5-15 cm. thick, were sterilized by heat applied for an hour, even when the central temperature had not reached 90 C.

CONSERVATIVE THERAPEUTICS *

THOMAS ORDWAY, M.D.
ALBANY, N. Y.

Notwithstanding the advance in medical science and the great improvement in medical education during the last twenty years, it is obvious that from the standpoint of the general public medical practice is not satisfactory. During the last few years, heated and conflicting criticisms of medical education by those in positions of authority have been factors in the formation of a commission on medical education to make a thorough survey of present requirements of medical practice. A not inconsiderable number of the people, including many otherwise intelligent persons, because of dissatisfaction with medical practice, go to the so-called cults, seeking relief from physical and mental difficulties.

In 1834, in a discourse on quackery, Dr. Zadok Howe pointed out the danger of the irregular practitioners whose energy at this time was devoted largely to the sale of "patent" vegetable remedies. He made interesting suggestions to check this evil, such as the diffusion of special education by the organization of lay societies, and opportunities for chemical examination of these remedies with reports of results. Such ideas carried out by the Council on Pharmacy and Chemistry, the publication *Hygeia* of the American Medical Association, and the work of the American Association for Medical Progress would seem to be carrying forward Dr. Howe's suggestions.

Even at this time, almost a hundred years later, the enormous advance in scientific medicine, with the remarkable development of surgical procedures and the discovery and application of methods of utmost importance in preventive medicine and public health, has led to neglect in medical teaching and practice of certain very valuable therapeutic aids. It has also created an intensive urge for the discovery of specifics and the premature announcement of amazing and false cures, by even the most prominent foreign and American university clinics.

Several years ago while I was in Europe making a urvey of cancer research with particular reference to he application of radioactive substances, a study of [illegible] literature supplied from well known university nics could with the greatest difficulty be differentiated [illegible] the advertisements of the most blatant quacks. his country, also, a glance backward reveals the ing and unwarranted publicity permitted even by university administrators announcing cures for various diseases, notably certain types of anemia, and infection, and particularly cancer. In some instances this has doubtless been due to the urge for funds that such publicity may supply, coupled with a feeling that the end justifies the means. In other instances, however, *it is surprising how uncritical prominent educators and* even learned chemists and physicists may be when dealing with biologic material; and when the added psychologic factor of the human being is introduced, the situation is even more confusing.

The American Medical Association sends the graduating class of medical students each year a code of personal ethics, "The Principles of Medical Ethics," a minimal standard which we believe necessary if medicine is to be regarded as a profession. Because of the far-reaching example and grave dangers of unwarranted claims and premature publicity just referred to, a code of ethics for our institutions would not seem out of place. How can we combat similar methods among the cults and irregular practitioners when such occurrences are only too common? In this connection I would commend the Lettsomian Lectures of Dr. E. F. Buzzard, recently published in the *Lancet.*

Conditions would be greatly helped if all practitioners and investigators established an ethical basis of procedure which required minimal criteria for diagnosis and treatment. Furthermore, in the treatment of every case we should constantly emphasize the dictum of Hippocrates that "the aim of the physician should be to do good to his patient, or, at least, to do no harm." If this is not true, what is the object of the practice of medicine? For if we regard our work as a profession, our purpose is not merely to strive for anatomic correction of defects, but to try to aid our patients in effective living.

Surgery will discover new methods, and pharmacology and immunology will assist in placing medicine on a more rational scientific basis; but there are to my mind two serious defects in our medical education and medical practice which have been potent factors in the development of the so-called cults—the neglect of the proper instruction and use of physical therapy, and the consideration and general application of psychiatry.

As physicians and investigators, we have not been foremost in acquiring the knowledge and in making suitable application of physical agents, but have left this for the most part to be developed by others. Indeed, in this subject, also, as is largely the case with drugs, vaccines and serums, the postgraduate education of practitioners has been taken over by uncritical commercial houses. Fortunately, a council on physical therapy has been formed during the past year by the

irman's address, read before the Section on Pharmacology and [illegible] at the Seventy-Seventh Annual Session of the American Association, Dallas, Texas, April, 1926.

Air Embolism with Criminal Abortion.—Hulst relates that in one of the two cases he describes death occurred instantaneously after the first symptoms of air embolism, but eighteen hours had elapsed since the intra-uterine injection of a warm fluid, responsible for it. No air was found in the fetal membranes but there was air between the uterus wall and the ovum (twenty-three weeks) which had been partially detached. In the other case, the broken tip of the syringe cannula had pierced the right wall of the vagina, and air had been injected directly into some injured blood vessel. Death was instantaneous, and air was found in the heart.

Pluri-Orificial Erosive Ectodermosis in a Woman. J. J. C. Schreuder.—p. 874.
International Cooperation in Medicine. F. H. Quix.—p. 898.

Psoriasis After Neo-Arsphenamine Treatment.—The young woman developed an arsenical erythroderma after a total of 5 Gm. of neo-arsphenamine had been injected, and psoriasis developed on this basis. After acute bilateral parotitis about a month later, the psoriasis subsided in a few weeks. It had responded to all the tests for true psoriasis.

Hour-Glass Stomach.—The woman of 51 had had more or less stomach disturbances for twenty years, with two temporarily successful courses of medical treatment for gastric ulcer. The pains finally became unendurable, with a hemorrhagic tendency, and the laparotomy revealed an hour-glass stomach with an ulcer that had invaded the pancreas, another ulcer at the pylorus, and a duodenal ulcer. After the extensive resection required, the woman gained 12.5 Kg. in weight, and has been free from all stomach disturbances during the eight months to date.

Canned Goods.—Van Leersum describes the exhaustive tests applied to a consignment of a canned food, a hash, including onions and potatoes, put up six years before. His expert testimony was to the effect that this canned food was suitable for the table. In the course of his research he became convinced that the indispensable element for conservation of foods in cans is to exhaust all the air from the can as it is sealed. The oxygen is responsible for any corrosion that occurs.

*Training in Medical Radiology. G. Forssell.—p. 73. C'cn.

The Larynx Test for Tubercle Bacilli.—Silwer and Rasch report that they were able to demonstrate tubercle bacilli in the secretion taken directly from the larynx in 17.4 per cent of 219 patients whose sputum was free from tubercle bacilli, or from whom no sputum was obtainable.

Training in Medical Radiology.—This was the opening address at the recent annual meeting of the radiologists of the Northland. Forssell in conclusion lists the opportunities throughout the world for instruction in this line.

88: 145-192 (Feb. 28) 1926

Neo Platonism and Medicine. E. Nachmanson.—p. 145.
*Surgical Treatment of Splenomegaly. A. Troell.—p. 157. Begun, p. 116.

Operative Treatment of Splenomegaly.—Troell states that the effect of splenectomy was satisfactory, both at the time and later, in most of his fourteen cases of Banti's disease, hemolytic jaundice or essential thrombopenia. Even Banti cases with urobilinuria, ascites and histologic changes in the liver may retrogress to clinical recovery. The prognosis does not depend on the stage of the process so much as on the grave anemia, even in recent cases; the outlook is better when the symptoms are referable more to the abdominal organs than to the blood picture. One of his eight Banti patients recovered after ligation of some of the vessels of the spleen, without removing the latter. This intervention should be considered when it is inadvisable to reduce the defensive forces as splenectomy might contribute to lower the resisting powers. One patient died during an attack of influenza a year after the splenectomy for Banti's disease, and, besides red bone marrow in the femur, all the cervical and abdominal glands were found enlarged. In the Banti cases he often found a history of jaundice and gastro-intestinal disturbances far in the past occasionally, the symptoms had developed first during a pregnancy. One of the two patients with pernicious anemia was treated by ligation of vessels, but this did not check the disease.

Ugeskrift for Læger, Copenhagen

88: 149-174 (Feb. 18) 1926

*Treatment of Diphtheria, 1921-1925. H. Heckscher.—p. 149. C'cn, p. 187.
Cancer of the Uterus. H Abrahamsen.—p. 159.
Pergola's Culture Medium for Diphtheria Bacilli. Nyfeldt.—p. 165.

Treatment of Diphtheria.—Heckscher's article is the third report on diphtheria from the Blegdamshospital in the last twenty-eight years. In the last nearly five years the mortality from diphtheria was 1.2 per cent of 4,819 cases. Circulatory insufficiency—diphtheria shock—was responsible for the fatality in all but five of the sixty-six deaths; paralysis of the respiratory muscles in four cases, and fatal toxic action on the liver and kidneys in one case. The rule is as large doses of antitoxin as possible, as early as possible, absolute quiet, camphor subcutaneously and caffein by the mouth. Further study of diphtheria shock may disclose means to act on the capillaries, arterioles or heart musculature, and show whether epinephrine might not help. To prevent serum sickness, injection of nonspecific proteins seems promising. Better results can be hoped for when the antitoxin is made more potent in smaller compass, so that larger doses can be given.

88: 175-208 (Feb. 25) 1926

*Results of Sanocrysin Treatment. K. Secher.—p. 175.
*Biologic Analysis of Digitalis Substances. Marie Krogh.—p. 183.
Small Doses of Metal Salts in Therapeutics. N. Lunde.—p. 191.
Glaucoma and Blindness in Iceland. P. Børresen.—p. 194.

Sanocrysin Treatment.—Secher reports 106 patients with various forms of tuberculosis free from all signs of active tuberculosis when dismissed from treatment; thirty-five were merely improved, and forty-six not benefited.

Biologic Analysis of the Active Principles of Digitalis.—Some of these substances are soluble in chloroform, others in alcohol, and the question is whether there is a similar difference between their biologic action. Krogh tabulates the findings in mice and frogs which have demonstrated a pronounced qualitative difference. The gitalin glucoside displays greater potency in mice. With a solution of gitalin and one of digitalin, both of which display the same potency in the frog heart, the gitalin solution has a threefold stronger action on the mouse heart. Similar qualitative differences are noted with the less readily soluble element digitoxin. The research reported is a link in the chain of the international standardization research now under way.

In this country, also, a glance backward reveals the amazing and unwarranted publicity permitted even by university administrators announcing cures for various diseases, notably certain types of anemia, and infection, and particularly cancer. In some instances this has doubtless been due to the urge for funds that such publicity may supply, coupled with a feeling that the end justifies the means. In other instances, however, it is surprising how uncritical prominent educators and even learned chemists and physicists may be when dealing with biologic material; and when the added psychologic factor of the human being is introduced, the situation is even more confusing.

The American Medical Association sends the graduating class of medical students each year a code of personal ethics, "The Principles of Medical Ethics," a minimal standard which we believe necessary if medicine is to be regarded as a profession. Because of the far-reaching example and grave dangers of unwarranted claims and premature publicity just referred to, a code of ethics for our institutions would not seem out of place. How can we combat similar methods among the cults and irregular practitioners when such occurrences are only too common? In this connection I would commend the Lettsomian Lectures of Dr. E. F. Buzzard, recently published in the *Lancet*.

Conditions would be greatly helped if all practitioners and investigators established an ethical basis of procedure which required minimal criteria for diagnosis and treatment. Furthermore, in the treatment of every case we should constantly emphasize the dictum of Hippocrates that "the aim of the physician should be to do good to his patient, or, at least, to do no harm." If this is not true, what is the object of the practice of medicine? For if we regard our work as a profession, our purpose is not merely to strive for anatomic correction of defects, but to try to aid our patients in effective living.

Surgery will discover new methods, and pharmacology and immunology will assist in placing medicine on a more rational scientific basis; but there are to my mind two serious defects in our medical education and medical practice which have been potent factors in the development of the so-called cults—the neglect of the proper instruction and use of physical therapy, and the consideration and general application of psychiatry.

As physicians and investigators, we have not been foremost in acquiring the knowledge and in making suitable application of physical agents, but have left this for the most part to be developed by others. Indeed, in this subject, also, as is largely the case with drugs, vaccines and serums, the postgraduate education of practitioners has been taken over by uncritical commercial houses. Fortunately, a council on physical therapy has been formed during the past year by the

---

* Chairman's address, read before the Section on Pharmacology and Therapeutics at the Seventy-Seventh Annual Session of the American Medical Association, Dallas, Texas, April, 1926.

American Medical Association. The personnel of this council is a guarantee that we shall have the same conservative and critical judgment in matters relating to physical therapy that has been of such great value as a result of the work of the Council on Pharmacy and Chemistry.

Nervous and mental conditions as a cause of disability are so common and manifest themselves under such varied physical disguises as frequently to elude the practitioner without special psychiatric training and interest. Indeed, we might add that almost every case of disease has a mental as well as a physical aspect, just as every human being has a mind as well as a body.

This idea of the interrelation of the physical and mental is expressed in the dialogue of Plato. It may be described as "mens sana in corpore sano." Jowett notes that "the Greek ideal of beauty and goodness, the vision of the fair soul in the fair body, is realized in the beautiful Charmides, and that the true conception of medicine is as a science of the whole, as well as the parts, and of the mind as well as the body: which is playfully intimated in the story of the Thracean: 'I daresay that you may have heard eminent physicians say to a patient who comes to them with bad eyes that they cannot cure his eyes by themselves, but that if his eyes are to be cured, his head must be treated; and then again they say that to think of curing the head alone, and not the rest of the body also, is the height of folly, and arguing in this way they apply their methods to the whole body, and try to treat and heal the whole and the part together.'"

A lack of the practical knowledge of applied psychiatry has caused many to claim good results by the most diverse types of treatment in similar pathologic conditions. It would surprise many of the searchers for hypothetic, or microscopic, foci of infection, or the advocates of specific measures in certain types of arterial hypertension, to realize how many of those and other diverse complaints are relieved by encouragement and reassurance, and by rest, fresh air, suitable food, adequate elimination and reeducation. Howk has recently emphasized the value of the treatment of heart cases in sanatoriums intended for the care of the tuberculous. I would heartily indorse his views and would add that opportunity for such care might properly be extended to those suffering from various other chronic physical as well as nervous conditions. Reeducation, particularly relating to environmental and vocational readjustment, is of the greatest importance in medicine and is frequenely lost sight of in the heedless application of so-called specifics.

In considering the value of any therapeutic agent, it is obvious that we should have precise knowledge of the diagnosis and of the natural history of the difficulty; for proper diagnosis and therapeusis we should therefore set for ourselves minimal criteria. In an attempt to determine the value of certain physical agents, such as radium and the roentgen ray, I have already advocated and employed definite minimal criteria. Only in this way can we secure reliable data for critical analysis to determine the real therapeutic value of these agents. Those who have had extensive experience with cancer realize that the chief difficulty with educational programs which have been of such value in tuberculosis is the paucity of facts at our disposal. In the case of tuberculosis, knowing certain definite and essential facts about etiology and pathogenesis of the disease, even though no specific cure has been found, the incidence and mortality has been greatly reduced by suitable education, early diagnosis, and attention to the cardinal principles of treatment referred to above. The records of life insurance companies are a fertile source of facts regarding the course of certain diseases, and a careful following of their preferred risks should add many additional facts.

We need a detailed knowledge of the natural history of many disorders; and unless we have such definite information as a basis for comparison, it is very difficult to judge the value of various therapeutic procedures. Of the incidence and course of less definite diseases we know very little; but a system of disability reports, carefully checked up in industrial plants and in private practice, should give us "controls," which are so important in therapeutics. This is particularly emphasized in the case of the common colds, about the etiology and therapy of which there is so much doubt, in spite of the assertions of all sorts of specific cures. Such knowledge should be of great help in lessening the incidence and mortality of pneumonia. I have modified and simplified a report blank used by the United States Public Health Service so that it may serve for a simple system of reporting the incidence and course of general as well as special disabilities.

Clinical therapeutic research should be an intensive search for the truth, with adequate controls as indicated above, because of the variability of the factors dealt with. In this connection it would be well if all could read again that outstanding address on self limited diseases by Dr. Jacob Bigelow before the Massachusetts Medical Society, May 27, 1835. In his concluding remarks, Dr. Bigelow states that if at times we seem to "accomplish comparatively little in the actual direction of the disease, the necessity becomes more imperative that we should do that little wisely and well. The importance and usefulness of the medical profession, instead of being diminished, will always be elevated exactly in proportion as it understands itself, weighs justly its own powers, and professes simply what it can accomplish. It is no derogation from the importance of our art that we cannot always control the events of life and death, or even of health and sickness. The incompetence that we feel in this respect is shared by almost every man on whom the great responsibilities of society are devolved. The statesman cannot control the destinies of nations, nor the military commander the events of battles. The most eloquent pleader may fail to convince the judgment of his hearers, and the most skilful pilot may not be able to weather the storm. Yet it is not the less necessary that responsible men should study deeply and understandingly the science of their respective vocations. It is not the less important, for the sake of those whose safety is, and always will be, committed to their charge, that they should look with unbiased judgment on the necessary results of inevitable causes; and while an earnest and inquiring solicitude should always be kept alive in regard to the improvement of professional knowledge, it should never be forgotten that knowledge has for its only just and lasting foundation a rigid, impartial, and inflexible requisition of the truth."

Centennial of Bromine.—The University of Montpellier is to celebrate in November the hundredth anniversary of the discovery of bromine by the professor of chemistry there, J. Balard.

BLOOD TRANSFUSION IN PERNICIOUS ANEMIA *

HAROLD W. JONES, M.D.
PHILADELPHIA

Blood transfusion in pernicious anemia produces better and more permanent results than any other therapeutic measure. Although transfusion has been used in this disease for many years, the early results were not satisfactory. The causes of these poor results were: (1) failure to cross agglutinate before each transfusion; (2) the use of improper methods of transfusion; (3) the injection of too large amounts of blood, and (4) too long an interval between transfusions. Many have said that transfusion did little good; others that it seemed to retard progress, and a few that it definitely shortened the life of the patient, all of which has served to bring discredit on this useful therapeutic measure.

TYPING AND CROSS AGGLUTINATION

The institution of typing by Shattuck, in 1899, gave added incentive to the use of transfusion by increasing its safety. However, the terms "universal donor" and "universal recipient" came into use. The belief that a so-called universal donor could safely give blood to any group and that a universal recipient could receive blood from any donor caused many hemolytic reactions. It was soon found that even though two persons were of the same type, it was possible that the serum of either might agglutinate the cells of the other. Cross agglutination was developed, and its use has distinctly lessened the number of serious reactions. Changes in the patient's type may occur following a transfusion, and it is therefore safer to cross agglutinate before each transfusion, even though the same donor is used.

METHOD OF TRANSFUSION

The citrate method was instituted by Lewisohn to offset the disadvantages of Lindeman's method; that is, coagulation in the instrument. It should seldom be necessary to add a foreign body, such as sodium citrate, to the blood if a method is available that permits of the transfusion of blood without coagulation. The Unger method fulfils this requirement. Moreover, the injection of 2 per cent sodium citrate solution has resulted in death. Blood platelets are destroyed when the citrate method is used, and reactions are more common with citrated blood than with whole blood. Because of these facts, the transfusion of whole blood should be the method of choice.

Many patients with pernicious anemia have very small veins, but it should seldom be necessary to expose the vein in order to insert the needle. Frequently, there may be only one or two available veins; and, if these are exposed, incised or tied off, it prevents their easy use at an early interval for further transfusion.

AMOUNT OF BLOOD TRANSFUSED

It has been the custom in the past, and still is in some clinics, to administer large amounts of blood at a single transfusion; that is, from 800 to 1,200 cc. This amount in a disease in which the total blood volume is not reduced places a strain on the circulation. The myocardium in pernicious anemia has degenerated and therefore the injection of such large amounts of blood is attended with danger. It has also been suggested that the injection of large amounts of blood may depress regenerative function.

Dr. Colwell of Pittsburgh employs small amounts of blood, from 20 to 50 cc., at frequent intervals. He finds that in many patients the blood elements can be increased thereby. My belief is that blood given in such amounts is useful between transfusions of larger amounts, when there is difficulty in obtaining a suitable donor. It may prevent a fall in red blood cells and hemoglobin until such time as a transfusion of a larger amount can be given. Fifty cubic centimeters of blood will not, however, furnish sufficient blood elements to reduce urgent symptoms materially, and the use of small amounts of blood is not likely to be of much benefit in such states. Enough blood should be introduced to lessen or remove the symptoms resulting from the deficient oxygen-carrying power of the blood.

The plan that I use is as follows: In urgent cases, in which the patients are unconscious or stuporous, amounts of from 450 to 600 cc. are given. To patients who do not suffer from such severe symptoms and whose hemoglobin is between 20 and 30 per cent, and the red blood cells from 700,000 to 1,000,000, approximately 100 cc. is given at the first transfusion. The same amount is used for the first transfusion when the anemia is less severe. Serious reactions very frequently follow the first transfusion, and the administration of a small amount of blood lessens this danger. It is also to be noted that if more than a week elapses between transfusions, reactions occur more readily.

INTERVAL BETWEEN TRANSFUSIONS

In pernicious anemia the hemoglogin and red blood cells are increased following a transfusion, but in from three to seven days, in most instances, a drop of these elements occurs. This reduction is often greater than the previous increase, bringing the blood count to a lower level than before the transfusion. Because of this, when the interval between the transfusions is too long, the good accomplished by a single transfusion is lost. The result is similar when a second transfusion is given. Recently, a patient was seen who had received six transfusions of from 500 to 800 cc. every two weeks, whose red blood cells and hemoglobin were lower after the series of transfusions than before. Permitting too long an interval to elapse between transfusions is responsible for more of the poor results in pernicious anemia than any other single factor. To overcome this, the transfusions are given every three to five days, thereby adding blood elements before there is a decided decrease. With the use of these smaller amounts of whole blood, from 350 to 450 cc., depending on the weight of the patient, from every three to five days, it has been possible to bring the red blood cells and hemoglobin to a normal point in nearly every instance. In addition, when smaller amounts are given, a donor can be used more frequently.

REACTIONS

Reactions may occur with whole blood transfusions. They are of several varieties: (1) chilly sensations; (2) a rise in temperature of from 1 to 2 degrees; (3) a chill plus a rise in temperature; (4) urticaria, pruritus, subglottic edema, or pulmonary edema; (5) mild hemolysis characterized by petechiae, and (6) severe hemolytic reactions, petechiae, ecchymosis, jaundice or

* Read before the Medical Section, College of Physicians, Philadelphia, Dec. 22, 1924.

hemoglobinuria. In the first four forms of reactions, the hemoglobin and red blood cells are not reduced. The hemolytic reactions are dangerous, and death may ensue.

There are difficulties which one is bound to meet in treating pernicious anemia by transfusion. If the patient is unfortunate enough to be a type I or type III (Moss), it may be difficult to find sufficient donors. Secondly, it may require from five to fifteen transfusions to bring about a normal blood count. It is seldom that the patient has a sufficient number of friends or relatives whose blood matches perfectly.

Results of Blood Transfusions in Treatment of Pernicious Anemia

	Sex*	Age	Normal Blood Count	Number of Transfusions	Relapses	Results	Time Since Last Transfusion	Time Since First Transfusion

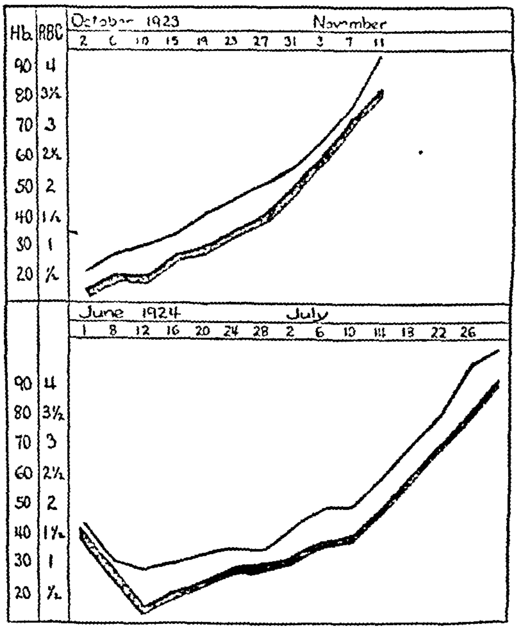
To obtain donors means the outlay of from $25 to $50 for each transfusion, and many cannot afford this. Then, too, until the hemoglobin is 50 per cent and the red blood cells 2,500,000, the improvement is usually much slower than after this point is reached. Sometimes several transfusions are given with seemingly very little improvement. These obstacles, however, are not insurmountable, and the results obtained warrant the effort. The results of some of our transfusions are given in the accompanying table.

RESULTS

Thirty patients were treated by transfusion; twenty are living; there were ten deaths.

Of the twenty living, the time that has elapsed since transfusion varies from a few weeks to seven years. The time elapsing from the date of the first transfusion varies from two months to seven years. In five patients, the blood has been brought to a normal count three times. In four patients, the blood has been brought to a normal count twice. Thirteen of the twenty patients are performing at least a part of their duties.

One patient in whom marked nervous phenomena developed was brought to a normal blood count three times in a period of fourteen months. Death resulted from pyonephrosis. The hemoglobin and red blood cells were practically normal at that time. One patient died of pneumonia. The blood count was normal. One patient, with a blood count nearly normal, died of a hemolytic reaction. One died because we were unable to get further donors for him. His blood count had been brought to normal twice. One patient refused more transfusions after being brought to a normal count twice. One patient, after being brought to a normal count twice, died six hours after a transfusion given at the beginning of the third relapse. One died two days after the first transfusion. This is the only patient whom we were not able to bring to a normal count at least once with transfusions when donors were available.



Results of transfusions in case 4. On each of the dates given, there was a transfusion of 400 cc. From November to June, the patient was well and working. Dec. 20, 1924, the patient was well, taking trips about the country, and in better health than for ten years. Light line, red blood corpuscles, heavy line, hemoglobin.

WHAT WE CAN HOPE TO ACCOMPLISH BY MEANS OF BLOOD TRANSFUSION IN PERNICIOUS ANEMIA

1. Life in those patients who present urgent symptoms can be saved.
2. Unpleasant symptoms can be alleviated and the patient given added strength and hope.
3. A so-called remission can be stimulated.
4. The patient can be carried along at a higher nutritional level with the hope that a remission will result. It is reasonable to assume that he has a greater opportunity to develop a remission when the blood is above 50 per cent than when it is between 20 and 50 per cent.

5. What appears to be a cure in an occasional patient can be brought about.

In order to accomplish these results, the following points must be observed:

1. A small amount of blood (100 cc.) should be given at the first transfusion to offset the possibility of death in a very few cases, unless the patient requires a larger amount to carry him past the danger point.
2. Whole blood should be used.
3. Moderate amounts of blood, from 350 to 450 cc., should be given.
4. In the hemolytic stage, the amounts should be increased daily, beginning with 50 cc.
5. Transfusion should be employed at four-day intervals.

VERY LATE ABSCESSES IN POSTOPERATIVE SCARS *

WILLIAM A. FISHER, Jr., M.D.
AND
HARVEY B. STONE, M.D.
BALTIMORE

It is well recognized that tissues which have become infected may be subject to recurrence of acute inflammation for considerable periods after their apparent complete healing. This principle was emphasized by experience with wounds during the war. It soon became apparent that corrective and cosmetic operations on scars of battle wounds that had been originally infected were very apt to relight the previous activity of the infection, sometimes with disastrous results. Accordingly, it became a generally accepted rule to postpone any such contemplated improvement in scars for a period of at least a year after the final healing of the original wound.

The same experience has resulted from operative treatment of joints and bones that had formerly been the site of infectious processes. For instance, tuberculosis of the joint may be stirred into renewed virulence by attempts to correct deformities years after all evidence of activity has subsided. This raises the question as to how late one may possibly find recurrences of inflammation in tissues which have seemingly been entirely free of infection for a long interval. Experimental work on this subject would scarcely be feasible, and it is therefore of interest and of considerable practical importance to call attention to the group of cases here presented and their direct bearing on the question at issue. It is a common experience that suppurating wounds, after they have apparently healed, may develop recurrent abscesses within several days or a few weeks. It is unusual for trouble to manifest itself later than this. We present four illuminating cases from our personal experience, with no attempt to search the literature for further examples.

REPORT OF CASES

Case 1.—*History.*—A white man, aged 37, had been operated on, Dec. 27, 1921, for gallstones. A diseased gallbladder and dilated common duct were found, with gallstones impacted immovably in the papilla of Vater; these gallstones were removed by a transduodenal incision and the wound was drained. The patient made an uneventful recovery and was discharged from the hospital with a completely healed wound in about five weeks.

Second Operation.—July 8, 1922, the patient returned with a large abscess in the old scar of about five days' duration. This was incised and drained, and a quantity of foul smelling pus with colon odor was evacuated; no foreign body, either gallstones or suture, was found. Unfortunately, no culture is recorded. The abscess cavity had dense scar tissue walls and evidently had formed within the old scar. The patient's postoperative condition was uneventful, and the drained wound healed promptly and has given no further trouble up to the present time. The interval between operations was six months.

Case 2.—*History.*—A white man, aged 28, was operated on, Dec. 6, 1922. A well walled off appendix abscess was found lying on the outer side of the ascending colon, which was drained. A gangrenous appendix was removed, and the wound was drained. The patient made an uneventful recovery, his wound having completely healed in about six weeks.

Second Operation.—July 25, 1924, the patient presented himself complaining of pain and tenderness in the scar of the old incision, which had been noticed for the past four or five days. It had all the clinical signs of an abscess. He was operated on, and thick, colon-smelling pus was evacuated. A small particle of foreign body about the size of a pin head, which may have been the remains of a fecal concretion, was found. The wound healed uneventfully, and there has been no trouble since then. Unfortunately, in this case also no cultures were recorded from the pus. The interval between the operations was eighteen months.

Case 3.—*History.*—A white boy, aged 12 years, was operated on, Aug. 1, 1919, for acute appendicitis; the usual removal of an acute unruptured appendix was done and the wound closed with silk sutures throughout. Healing was apparently by first intention and the patient was discharged as being well. After a few days at home an abscess developed in the wound, which was opened and a black silk suture was discharged. This closed in a few days and the wound then appeared to be completely healed.

Second Operation.—The patient had no trouble from his old incision until a short while before Dec. 9, 1925. He then began to complain of some tenderness about his old scar, and it was examined by several physicians; there was found a distinct, firm swelling under the skin scar, slightly tender on pressure and not noticeably changing on coughing or straining. There was some difference of opinion as to the exact nature of this condition, the two probabilities being postoperative hernia becoming incarcerated, or a recurrent abscess in the scar. The last opinion was the one considered more probable. December 9, the scar in the skin was excised, and the skin and subcutaneous fat were found normal, but under the aponeurosis of the external oblique was found an abscess with very dense fibrous walls containing about 2 drachms (7.5 cc.) of thick creamy pus, which was odorless and from which a growth of *Bacillus alkaligenes* was obtained. A small black particle, which was at first thought to be a remnant of silk ligature, proved to be a fragment of blood clot. The wound healed in a very short time and there has been no further trouble. The interval between operations was six and one half years.

Case 4.—*History.*—A white man, aged 46, was operated on June 3, 1912, for right inguinal hernia. The usual operation was done and silk sutures were used in the closure throughout. The only complication in the postoperative course was a cystitis following catheterization. The wound at no time showed any evidence of infection.

Second Operation.—During the summer of 1919, the patient had swelling, pain and tenderness in the scar, of a few days' duration. This was opened by an incision, and a quantity of pus was discharged and with it a silk suture from the depth of the wound. The wound drained for a few days and healed promptly; there has been no subsequent trouble. The interval between operations was seven years.

COMMENT ON CLINICAL FACTS

Previous Infection.—Of these four cases, one was in origin a heavy infection, with drainage—case 2, gangrenous appendicitis with localized abscess. In case 1 there was potential infection, and drainage was done; a gallstone in the papilla of Vater was removed by the transduodenal approach. In case 3 there was a history of stitch abscess during convalescence from appendectomy. Case 4 was a clean hernia operation without any evidence of postoperative infection so far as the wound was concerned. This incidence of a previous infection of the wound in three out of four cases is of great significance, but perhaps of more arresting interest is the fourth case with no such antecedent history and yet with a definite abscess very late after operation and the discharge of a foreign body. Further discussion of the problems here involved will be advanced later.

---

* From the Surgical Department of the Johns Hopkins University Medical Department.

Location of Scars.—It will be noted that all four of these operations involved the soft parts of the abdominal wall, with no involvement of bone or joint.

Character of Secondary Abscesses.—All the abscesses contained frank, creamy, "laudable pus"—not simply serum or serosanguineous exudate. A foreign body was found in the single case which had no history of a previous infection at the original operation, and also in the appendix abscess case. No fistula into a hollow viscus, and no implication of any abdominal organ was observed in any of the secondary abscesses. Unfortunately, bacteriologic study of these cases is sadly deficient. Two presented distinct colon odor of the pus, but the hospital records show no report as to cultures. In a third case the abscess was opened in the private office of one of us, and no cultures were made. The remaining abscess gave a growth on culture that was identified as the unusual organism—at least in surgical experience—*B. alkaligenes.*

Clinical Course of Cases.—These patients all presented the clinical signs of ordinary abscesses except in case 3, which lacked any very acute signs of inflammation, and in fact was not positively diagnosed as such, although this was considered the most likely diagnosis. This case was also the one from which *B. alkaligenes* was grown. All these abscesses healed promptly after the evacuation of pus, and no subsequent trouble has arisen in any of them.

A summary of the cases will show that, in periods running from six months to seven years, abscesses may make their appearance in tissues that were formerly operated on but which have apparently completely returned to normal in that interval. One must consider several possibilities in an attempt to reach an explanation of these facts. In the first place, it may be a mere coincidence that an abscess should pick out for its locus the scar of the former operation, just as an abscess may occur from various causes in any other portion of the body. This explanation is mentioned merely to include all the possible theories to account for such occurrences. It will not impress many as being highly probable. The second and a much weightier explanation is that scar tissue anywhere is a less resistant structure than normal tissue to the development of infection, and that this recurrent abscess may not be in the strict sense recurrent; in other words, a new infection may select scar tissue because of the known susceptibility of scar to injury of any sort. Case 3 was that of a boy who passed through an attack of measles shortly before operation for his abscess, which may lend some color to this idea; the implication being that, with measles, an infectious disease in itself, and with a lowered local resistance in the scar, the combination was provided which led to the development of the abscess. Case 4 is of even greater significance. This patient had no known infection of his original wound, yet seven years afterward an abscess developed about a silk stitch buried in old scar. This would seem strong evidence for the explanation of some cases at least as abscesses—not recurrent but de novo—in tissues of impaired vitality, with the added factor of nonabsorbable foreign bodies to aid in the development of infection.

A third, and in our opinion the most acceptable, conception of the process under consideration is that the tissues harbor in the site of the scar a persistent contamination with living organism during all the period of apparent quiescence. During this period the virulence of the bacteria is so feeble, and the general and local health of the tissues is so good, that a condition of balance is maintained, permitting the organisms to remain alive and presumably to multiply sufficiently just to sustain themselves, but on the other hand keeping them in such check that they are unable to cause any clinical symptoms of trouble. Then for some reason this balance is disturbed. This reason may conceivably include a great many possibilities concerning the local or general health of the tissue or the virulence of the organism. As a result of the disturbance, the bacteria take on renewed activity, become sufficiently virulent to give rise to acute inflammatory changes, and the clinical development of an abscess results. It would be unnecessary to attempt a detailed consideration of all the possible occurrences that may cause the balance to be upset: One at once thinks of general illness that lowers the health of the patient, of local injuries to the scar, and of changes in the body chemistry disturbing the intricate system of resistance to infection. Speculation along these lines is probably not profitable, although it may be interesting. The point that we wish to emphasize is the fact that these cases bear out in a brilliant manner the same clinical experiences already referred to in the opening of this paper, which has been illustrated by the war wounds and infected joints and bones; namely, that tissues once infected may harbor for a surprisingly long period organisms still potentially virulent, and that even as late as seven or eight years afterward renewed activity may take place.

Local Health Organization.—The exact plan of local health service that will fulfil all the essential requirements of any selected community must be adapted to the circumstances and conditions peculiar to that community. Because of climatic, geographic, political, social, racial, economic or other purely local characteristics, the vital health problems of one city may well differ from the particular problems that are of especial concern to some other city. This idea has led at times to the conclusion that it is impracticable to propose any standard or uniform basis for health department organization. As a matter of fact, however, many of the obstacles to be overcome in developing an adequate and comprehensive plan for community health service are imaginary rather than real ones. Man is subject to certain diseases and disturbances that obey rather fixed laws, irrespective of purely local conditions. In spite of such considerations, the essential public health problems in different cities differ not so much in their nature as in the comparative magnitude of the problems presented. There are certain basic requirements that should be fulfilled in practically every community, so that it is possible, therefore, to propose a more or less "ideal" health service that will at least represent minimum requirements.—Cumming, Hugh: *Pub. Health Rep.* **41**:372 (Feb. 26) 1926.

THE INTRACUTANEOUS SALT SOLUTION TEST

ITS USE AS A TEST OF THE EFFICIENCY OF THE CIRCULATION IN THE EXTREMITIES *

MILTON B. COHEN, M.D.
H. S. APPLEBAUM, M.D.
AND
E. L. HAINSWORTH, A.B.
CLEVELAND

In May, 1925, one of us[1] reported that the intracutaneous salt solution test, as devised by McClure and Aldrich[2] for the study of edema, afforded a simple method of determining the efficiency of the circulation in the extremities. The present report deals more fully with the nature of this reaction and with its clinical applications.

NATURE OF TEST AND MECHANISM OF ACTION

When 0.2 cc. of an 0.85 per cent salt solution is injected into the skin of a normal individual, sixty minutes or more is required for its complete absorption. In cases showing edema, the disappearance time is decreased in direct ratio to the degree of edema, and in extreme cases the injected fluid disappears so rapidly that it is impossible to produce a wheal. These observations hold true for all edema, whether it is of the so-called renal or cardiac types.

Aldrich[3] discusses the mechanism of this reaction and concludes that in cases of edema there is an increased affinity of the tissues for water. The injected salt solution is more rapidly taken up in edema because the tissues, needing more water, take it from the most available source, in this instance, the wheal produced by the injection. This explanation is based on the work of Martin H. Fischer,[4] who in 1908 first called attention to *the rôle of the tissues in the production* of the edemas. He postulated that the normal turgor of a tissue depended on the physical state of its colloids, and that edema resulted whenever the water holding power of its colloids was increased and there was an available supply of free water. This state could be brought about during disease processes by accumulation in the tissues of acids, amines or substances having a similar action. This theory was severely criticized by most of the recognized workers in medicine and the allied sciences, as it was a current belief that edema was the result of increased permeability of blood vessels and an increase in the intravascular pressure. These observers stated that they could not demonstrate any acidosis in the blood or tissue fluids by microchemical analyses, and therefore denied its existence in early edema and its relation to edema. Fischer has always maintained that one might have localized acidosis without any evidence in the blood, as determined by the usual methods of analysis, and recently this has been proved by Rous,[5] who demonstrated localized cutaneous acidosis in many conditions. In general, he found that all agents that interfered with tissue oxygenation produced this condition, which he called "outlying acidosis."

Subcutaneous injections of epinephrine were shown by Rous to produce outlying acidosis in the skin of a rat. The following experiment illustrates the effect of this substance on the salt solution disappearance time:

In a normal individual, 0.2 cc. of 0.85 per cent salt solution was injected intracutaneously in the right thigh. It disappeared in sixty-five minutes. A similar injection was made 15 cm. away from the first. Then 1 cc. of 1:5,000 solution of epinephrine was injected subcutaneously in the region of the wheal. This wheal required only forty-five minutes for its complete absorption A third wheal produced by the intracutaneous injection of 0.2 cc. of 1:5,000 solution of epinephrine disappeared in thirty minutes.

Pilcher[6] has shown that the size of the wheal produced as a result of the intracutaneous injection of *morphine can be reduced by subcutaneous injections* of epinephrine, an observation that is the corollary of the foregoing finding.

There is good experimental evidence, therefore, for the belief that there is an increase in the rate of absorption of water from areas of localized acidosis and that such acidosis is commonly produced by anoxemia.

Localized acidosis can be produced by obstruction to the venous return just as readily as by inadequate arterial blood supply, as the stasis soon produces the latter condition. Patients with varicose veins afford interesting opportunities for study of the effect of stasis on the salt solution disappearance time, as the degree of stasis and its duration can be regulated by changes in position of the legs. The following protocol illustrates such a case:

In a patient with marked varicose veins of both legs with slight edema of each leg from the knee down, a standard wheal was produced on each side, at a point 5 cm. above the ankle. The patient was lying in bed. The wheal disappeared from the right side in five and one-half minutes, and from the left side in fifteen minutes.

The legs were then allowed to hang over the edge of the bed, with the patient sitting up. The test was repeated immediately. There was a marked increase in the cyanosis of both feet, and the veins were engorged. The wheal disappeared from the right side in two and one-half minutes and from the left side in eight minutes. The difference in stasis, i. e., the increased anoxemia produced by the change in position, halved the disappearance time.

CLINICAL APPLICATION

In cardiac disease during decompensation there is a stasis, especially in the dependent structures, which is comparable to that observed in cases showing varicose veins. During the decompensation, the disappearance time is lessened in the edematous areas, though it may be quite normal in areas such as the skin over the deltoid, where the circulation is adequate. As the circulation improves, the disappearance time increases. From a study of a number of cases tested during decompensation and after it had cleared up, it has been determined that pitting over the shins never occurs with a disappearance time over twenty-five minutes, and that it can usually be detected when the time has been reduced to twenty minutes or less.

In peripheral vascular disease also, the disappearance time is decreased in proportion to the degree of anoxemia produced by the vascular involvement. This is well illustrated in cases of intermittent claudication, diabetic gangrene and thrombo-angiitis obliterans, as the following protocols will demonstrate:

P. D., aged 38, a Russian Jew, was admitted to the hospital, July 8, 1925, complaining of severe pain in the calves of the legs on walking. The pain came on after walking about 300 yards, and was so severe that he could not proceed but was forced to rest. In a few minutes the pain disappeared and walking could be resumed, only to be again interrupted after exercise. The pain was most marked in the right leg.

Physical examinations and the usual laboratory tests revealed no serious organic disturbances. The dorsalis pedis and posterior tibial arteries could not be palpated on either side. The Pachon oscillometer showed marked diminution in the circulation in both legs from the lower third of the thigh down, most marked on the left. The results of the salt solution test on the day of admission are given in table 1.

Table 1.—*Results of Salt Solution Test in First Patient*

	Right Leg, Minutes	Left Leg, Minutes
Base of great toe	5	9
	16	13
Ankle	24	48
	21	77
	72	78
Below knee	80	85
Above knee	78	80

A diagnosis of Buerger's disease with intermittent claudication was made, and sympathectomy was advised. Periarterial sympathectomy was performed on the right femoral artery, July 13. The next day the reading at the base of the right great toe was twenty minutes, and on the second day following the operation it had risen to forty minutes.

A. B., a woman, aged 58, was admitted to the hospital, June 4, 1923, because of superficial gangrene of the left great toe, occurring in the course of neglected diabetes. Under dietetic management the toe healed, and she was discharged to the outpatient department. She was readmitted one year later, in June, 1924, with a recurrence of the same condition. The lesion healed again under appropriate conservative treatment. April 14, 1925, she was admitted for the third time with a similar process involving the right great toe. The necrotic material was infected, and the whole foot was swollen. Her general condition was poor, as there was marked arteriosclerosis with hypertension but without nephritis. The left foot, which had been involved on the two previous occasions, showed the loss of small bits of the distal phalanges of the two inner toes. The peripheral pulses on this side were palpable. On the gangrenous right side, no pulses could be detected in the popliteal, dorsalis pedis or posterior tibial vessels. The results of the salt solution test performed two days after admission are given in table 2.

Table 2.—*Results of First Salt Solution Test in Second Patient*

	Right Side, Minutes	Left Side, Minutes
Middorsum of foot	15	55
Ankle	45	60
	60	70
	65	70
	65	80
Below knee	70	80
Above knee	70	80

Because of the relatively good results previously obtained by conservative treatment in this case and the small reduction in circulatory efficiency as indicated above, medical treatment was carried out. The gangrene spread slightly during the next two weeks. The infection did not respond well to the treatment, and the patient was septic. The salt solution test was repeated on the fifteenth day, with results as given in table 3.

From the result of the second test, it was obvious that the circulatory deficiency was increasing in the right leg, and that in the left leg gangrene was impending if the deficiency continued to increase. On the fourth day following this test, gangrene set in in the left foot. Five days later the test was repeated with results as given in table 4.

Table 3.—*Results of Second Salt Solution Test in Second Patient*

	Right Side, Minutes	Left Side, Minutes
Middorsum of foot	9	25
Ankle	17	35
	20	39
	27	62
	36	65
	41	68
Below knee	44	68
Above knee	51	70

On the next day both legs were amputated at the junction of the middle and lower thirds of the thigh.

The pathologic report showed very marked atherosclerotic changes in the femoral popliteal peroneal and anterior tibial vessels with occlusion of the last two in places by medial sclerosis and plaques. All of the vessels were markedly narrowed. The posterior tibial artery was almost entirely obliterated by endarteritis. The left leg showed a picture similar to that shown by the right. All vessels from the popliteal space down were narrowed and occluded in places by plaques.

In this case changes in the clinical condition of the patient were accurately followed by means of the salt solution test, and the oncoming gangrene of the left leg was indicated several days before it became manifest.

Table 4.—*Results of Third Salt Solution Test in Second Patient*

	Right Side, Minutes	Left Side, Minutes
Middorsum of foot	7	12
Ankle	7	12
	8	13
	12	14
	17	15
	39	18
	45	23

An interesting case which illustrates the value of this test in differential diagnosis was reported to us by Dr. Walter G. Stern:

A man, aged 62, was crushed between the bumpers of two street cars. On admission to the hospital he was in profound shock; the right thigh was tremendously swollen, purple and cold. No peripheral pulses were palpable in the injured leg. The clinical diagnosis depended on differentiating between shock and massive hemorrhage from rupture of the femoral artery. The intradermal salt solution test showed a disappearance time within normal limits, and a diagnosis of shock without rupture of the femoral artery was made. The patient died, and at necropsy the hemorrhage was found due to muscle injury and not to rupture of any large vessel. It was by means of this test that the surgeon was spared the embarrassment and the patient the further injury of an operation.

CONCLUSIONS

1. The intradermal salt solution test is a rapid and accurate method of determining tissue affinity for water.
2. Sixty minutes or more is the normal disappearance time.
3. In all conditions associated with localized anoxemia, the salt solution disappearance time is decreased.
4. In cardiac disease with decompensation, the disappearance time is always twenty minutes or less in

the edematous areas. If there is no decompensation, normal values are obtained.

5. In cases with peripheral arterial disease, the disappearance time is always decreased in areas showing clinical involvement. From observations in thirty-five cases, it has been noticed that readings below ten minutes have been found only in tissues immediately above areas of gangrene. Readings between ten and twenty-five minutes are strongly suggestive of developing gangrene.

THE TREATMENT OF CARDIAC PAIN BY PARAVERTEBRAL ALCOHOL BLOCK *

GEORGE I. SWETLOW, M.D.
AND
SIDNEY P. SCHWARTZ, M.D.
NEW YORK

In recent years the surgical treatment of cardiac pain has received much attention. The objective of the surgeon is to sever the pathway that conducts pain stimuli from the heart to consciousness. The identification of this pathway is based largely on comparative neuroanatomic studies. These investigations show that these structures vary not only in different animals but in man as well. Because of the insufficiency of the anatomic knowledge, as many as eight different operations have been devised for the relief of cardiac pain. The following briefly summarizes the operations that have been performed:

Cervical sympathectomy, including resection of the stellate ganglion on the left side and at times bilaterally.[1]

Section of the depressor nerve on the left side and at times bilaterally.[2]

Section of the sympathetic cord above the stellate ganglion on the left side.[3]

Section of a nerve fiber emerging from the vagus nerve on the left side alone or at times bilaterally.[4]

Cervical sympathectomy without resection of the stellate ganglion on the left side and at times bilaterally.[5]

Resection of the sympathetic cervical cord (without the inferior cervical ganglion) completed by section of the cervical vagus branches which enter into the thorax as well as the so-called vertebral nerve and the rami communicantes, which unite the stellate ganglion with the sixth, seventh, eighth cervical and first dorsal nerves.[6]

Section of the cervical sympathetic, together with the superior cardiac nerve on the left side.[7]

Section of the cervical sympathetic above the inferior cervical ganglion, including section of the vertebral nerve on the left side.[4]

This enumeration gives ample evidence of the insufficiency of the anatomicophysiologic knowledge of the pathway of pain from the heart to the thalamus, and suggests sharply an uncritical attitude on the part of those who subject patients to an operation based on such fragmentary understanding. Sir James Mackenzie [8] has bitterly opposed reckless operative intervention based on such meager scientific data.

In reviewing the operative results, conflicting and discouraging information was obtained. In a series of sixteen cases, Coffey and Brown [7] reported that only six patients were completely relieved; that there was a mortality of 12 5 per cent; that the operative residua, i. e., Horner's syndrome, severe constant sharp pain over the left half of the head, chest and left arm, were frequent and troublesome. Jonnesco [9] in his operations showed graphically the dangers of operative intervention in the absence of any adequate knowledge of the physiology of the cervical sympathetic. Two of his patients died from pulmonary edema four hours after the operation; one was found dead the day following operation with the same phenomenon of pulmonary edema; another was found dead in his bed the morning following the operation; a fourth died several hours after; a patient of Hofer's died fifteen hours after the same operation These represent only a few of the fatalities following operative intervention of the sympathetic for relief of angina pectoris.

It is our purpose to report on the use of paravertebral alcohol injections into the dorsal root ganglions and rami communicantes as a more rational and absolutely safe procedure for the relief of cardiac pain. Procaine has been injected paravertebrally for relief of angina pectoris and aortalgia by Danielopolu and Hristide,[10] Luger,[11] Pal,[12] Brun and Mandl,[13] Mandl [14] and Kappis.[15]

The employment of paravertebral alcohol block to relieve pain in malignant disease [16] of the chest as well as in a variety of other conditions [17] has given us such gratifying results that its use in the different types of cardiac pain seemed worth investigating.

THEORY ON WHICH METHOD IS BASED

Nearly all pain impulses, irrespective of their point of origin and of their pathway in the spinal cord, ultimately enter the spinal cord through the dorsal root ganglions. Constant stimulation of the small cells in the dorsal root ganglions by impulses coming from the heart is referred to the skin segments supplied by the respective ganglions, which in turn refer this irritation to the consciousness as pain. The axons of these small cells are unmyelinated and form fibers which convey protopathic stimuli. The introduction of alcohol into these irritable nerve fibers produces a wallerian degeneration. The site of the injection is determined by carefully mapping out skin areas of hyperesthesia, hyperalgesia and hyperthermesthesia on the chest wall. The nerve roots and dorsal root ganglions that supply the areas of *increased epicritic and protopathic sensibility* are presumably the ones kept in a state of irritation by the bombardment of afferent impulses from the heart. With the usual technic of paravertebral injections, from

3 to 5 cc. of an 85 per cent solution of alcohol is injected into the nerve roots identified by the foregoing procedure.

REPORT OF CASES

Case 1.—*History.*—R. C., a woman, aged 20, with aortitis and aortic insufficiency caused by congenital syphilis, began to complain of pain in April, 1923. In the beginning, the pain appeared over the precordium. In a few months the discomfort extended to the left shoulder blade and down the left arm and the back of the chest on the left side. The arm pain was sticking and constricting in character and especially worse during the night. Since April 17, 1924, the pain had been much more severe. The attacks consisted of paroxysms of severe sticking pains lasting a few minutes and leaving in their wake a dull ache over the same area. These paroxysms were brought on with only slight exercise, and as a result greatly curtailed physical activities.

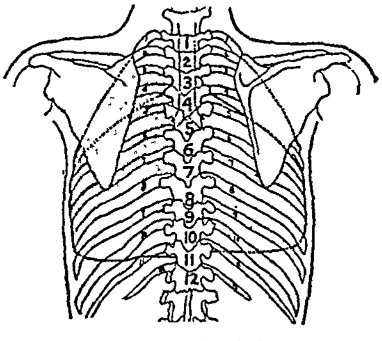

Fig. 1.—Sensory findings before injection.

She received a course of arsphenamine and mercuric salicylate, which was completed, Oct. 2, 1924; potassium iodide, which was discontinued several months ago, and a series of injections of bismuth subsalicylate.

Following this series of treatments she was slightly more comfortable, but the pain still persisted. A paravertebral alcoholic injection was performed, April 23, 1925. After the injection into the fourth, fifth, sixth and seventh dorsal roots on the left side, the patient was almost completely relieved of pain, and in addition was able to carry on increased physical activity to exhaustion without attacks of pain.

For example, before the injection of alcohol she was unable to walk more than one block without developing sharp, excruciating, sticking pain over the left chest anteriorly and posteriorly, with radiation to the left arm as far down as the hand. The pain was so severe that she was forced to stop, the distress lasting two or three minutes at a time. At present she is able to walk from five to ten blocks, and although she at times develops pain, she asserts that it is so mild and fleeting that she pays but little attention to it. Previous to the alcoholic injection she found that on attempting to practice on the piano more than ten or fifteen minutes she would be forced to stop because of the agonizing pain. Now she is able to play for at least one hour and at times more. Only occasionally has she a fleeting short pain over the left precordium.

Sensory Findings.—April 22, 1925, before the injection:

A. Epicritic sensibilities.
   1. Hyperesthesia to light touch with cotton wool extended from the third to the seventh dorsal nerves on the left side anteriorly and posteriorly.
   2. The patient was able to discriminate temperatures ranging between 26 and 38 C. over the same region.
   3. Cutaneous localization was well performed.

B. Protopathic sensibilities.
   1. A zone of hyperalgesia to pin prick extended from the third to the seventh dorsal nerves on the left side.
   2. A marked hyperthermalgesia was observed on the left side of the chest to temperatures above 45 and below 20 C. when compared to the right side. She was able to recognize these extreme differences in degrees on the left side.

June 1, thirty-nine days after the injection:

A. Epicritic sensibilities.
   1. A zone of hypesthesia to light touch with cotton wool extended from the third to the seventh dorsal nerves on the left side. In fact, she hardly perceived the stroke of the cotton wool.
   2. She was definitely unable to discriminate over the injected segments temperatures ranging from 26 to 38 C.
   3. Cutaneous localization was greatly impaired.

B. Protopathic sensibilities.
   1. An area of hypalgesia to pin prick extended from the third to the seventh dorsal nerves on the left side.
   2. A marked hypothermalgesia was found on the left side extending from the third to the seventh dorsal nerves when compared with the right side. There was great impairment in her ability to discriminate between extremes of temperature on the left side, i. e., between 20 and above 45 C.

Conclusion—1. Before injection, a zone of dermatomic irritability extended from the third to the seventh dorsal nerves on the left side. Sensory examination thirty-nine days after the injection showed that the nerve conductivity was greatly reduced.

2. The patient had been free from pain for four months when she was discharged from the hospital. Oct. 25, 1925, we received a letter from her in which she reported that she is able to walk distances as long as a mile without the appearance of pain.

Case 2.—*History.*—F. S., a man, aged 63, with angina pectoris due to coronary sclerosis, complained for the first time fifteen months before admission of a severe boring, retrosternal pain which penetrated anteroposteriorly. Frequently he observed that the pain was burning in nature, simulating "a feeling of hot sand." At times it was so excruciating as to induce crying. The pain would persist from twenty to twenty-five minutes, requiring morphine for its control. He could not walk any farther than three blocks at a time, for if he did, agonizing pain ensued. Twice this necessitated his being taken from the street to a hospital in an ambulance. Inhalation of amyl nitrite often relieved the attacks. Several months before we saw him he felt for the first time slight burning paresthesia down the left upper extremity.

June 25, 1925, he received a paravertebral injection of alcohol into the third, fourth, fifth and seventh intercostal nerves on the left side. Five cubic centimeters of an 80 per cent alcohol solution was used in each dorsal root. Following the injection, the pains were completely relieved within twenty-four hours. There was practically no limit to his ability to walk. He was up and about most of the day doing errands in the hospital, and definitely asserted that he was relieved of his pain. Nevertheless, he complained of shortness of breath when he exerted himself unduly, which was a very prominent symptom.

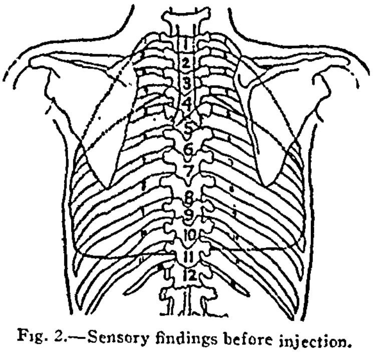

Fig. 2.—Sensory findings before injection.

Sensory Findings.—June 23, 1925, before the injection:

A. Epicritic sensibilities.
   1. A zone of hyperesthesia to light stroking with cotton wool was found over the skin supplied by the second to the eighth dorsal nerves on the left side both anteriorly and posteriorly.
   2. No disturbance was observed in his ability to discriminate temperatures ranging between 20 and 38 C. He had no difficulty locating areas lightly touched.

B. Protopathic sensibilities.
   1. An area of skin hyperalgesia to pin prick extended from the second to the eighth dorsal nerves on the left side.

    2. An extreme hyperthermalgesia was present on the left side when compared with the right side. He was able to distinguish these extremes of temperature on the left side.

October 24, 183 days after injection:

- A. Epicritic sensibilities.
    1. The patient hardly perceived being touched with cotton wool when stroked lightly over the dermatomic segments supplied by the injected nerves.
    2. He was unable to discriminate temperatures ranging between 20 and 38 C.
    3. Cutaneous localization was completely lost.
- B. Protopathic sensibilities.
    1. The patient could not feel the pricking of a pin over the areas of the skin supplied by the injected nerves. He experienced a peculiar dysesthesia; as he put it, "dull and frozen" when a pin was drawn across the skin.
    2. His inability to discriminate the extremes of temperature was quite marked. In fact, there was an almost complete analgesia.

Conclusion.—1. Before injection, a dermatomic zone of irritability was delineated. This extended on the left side over the skin supplied by the second to the eighth dorsal nerves. A sensory examination 183 days after the injection indicated that the nerve conductivity was greatly decreased.

2. He was completely relieved of all pain for a period of four months, when it again appeared. Reinjection was done, this time blocking the first, second, third and fourth dorsal root ganglions and rami communicantes. Before the second injection, the level of root hyperirritability was from the first to the third dorsal root segments. Following the injection, signs of diminished conductivity were noted. He is now again comfortable and free from all pain. He complains, however, of a pressing sensation over his shoulders when he attempts to rise from a sitting position, as well as slight retrosternal pressure.

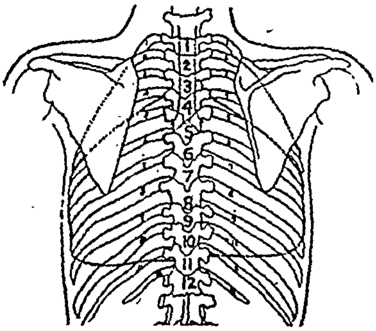

Fig. 3.—Sensory findings before injection.

Case 3.—*History.*—Y. S., a woman, aged 18, suffered from mitral stenosis and insufficiency together with cardiac decompensation. Fifteen months before admission she developed precordial pain for the first time. She described it as sticking in character, lasting from a few minutes to as long as an hour. At times the attacks of pain would appear during the night, awakening her from sleep. She complained that with the sticking pain there was a burning sensation in the skin. These attacks would appear for a few successive days and then disappear, only to reappear again. However, for four months preceding our treatment, the pain had been persistent, always more or less severe. During the ten days before injection the agony was especially disturbing, being both sticking and constricting in type, with no remission either by day or by night. The pain was particularly severe in the left interscapular region, preventing her from reclining on her back. June 25, 1925, 4 cc. of a 60 per cent alcohol solution was injected into the third, fifth, seventh and ninth dorsal roots. After the injection she experienced precordial pain only occasionally, and that which she did feel was slight and fleeting in character. She was able to recline on her back without pain or discomfort over the precordium. Within one week of injection she observed a peculiar itching paresthesia over the site of the injection. On scratching it she noted that there was very little sensation induced when she rubbed the skin.

Sensory Findings.—June 23, 1925, before the injection:

- A. Epicritic sensibilities.
    1. The dermatomic skin areas extending from the third to the eighth dorsal nerves on the left side both anteriorly and posteriorly showed a marked hyperesthesia. She noticed that light stroking with cotton wool induced an unpleasant scratching sensation.
    2. Her ability to discriminate temperatures varying between 20 and 38 C. was normal.
    3. Cutaneous localization was well performed.
- B. Protopathic sensibilities.
    1. A dermatomic zone of hyperalgesia extended from the third to the eighth dorsal nerves on the left side.
    2. In the same dermatomic zone hyperthermalgesia was observed in comparison to the right side. Temperatures below 20 and above 45 C. were used. There was no disturbance in her ability to recognize extreme temperatures on the left side.

September 11, seventy-eight days after the injection:

- A. Epicritic sensibilities.
    1. There was no disturbance in her ability to feel the light touch of cotton wool.
    2. There was no disturbance in her discrimination of temperatures ranging between 20 and 30 C.
    3. Cutaneous localization was unimpaired.
- B. Protopathic sensibilities.
    1. Her reaction to pin prick on the left side was only slightly below normal.
    2. Her ability to discriminate on the left side between extremes of temperature, i. e., below 20 and above 45 C., was greatly impaired. When compared with the right side there was a definite hypothermalgesia.

Conclusion.—1. This patient was injected with a weaker alcohol solution, i. e., 60 per cent.

2. The sensory findings after the injection showed the conductivity of the dorsal nerves to be only slightly decreased as compared with the previous two cases, in which an 80 per cent solution was injected.

3. The patient was free from all pain for fourteen weeks, finally dying from cardiac decompensation.

Case 4.—*History.*—J. W., a man, aged 61, suffering from angina pectoris associated with coronary disease and cerebral thrombosis, had for the past four years been complaining bitterly of precordial pain. At first the distress was brought on by walking two blocks, and caused such pain that he had to pause to rest. As time passed, he observed that walking even much shorter distances induced pain. He described this pain as sticking, tearing and at times constricting in character. These attacks would appear two or three times daily, each lasting from twenty to thirty minutes. For the past eighteen months he had been unable to walk more than 20 yards because of the induced agony. Every morning at about 2 o'clock he was awakened by severe precordial pain persisting from thirty minutes to an hour. He sat up in bed grasping the precordium. Occasionally he had a fear of impending death. June 12, 1925, a paravertebral alcoholic injection was performed. An interesting phenomenon occurred while the patient was on the operating table. He suddenly started to groan with pain, which was localized to the precordium. Accompanying this excruciating agony he became cyanotic. While he was in the throes of this anguish, 5 cc. of 1 per cent procaine solution was introduced paravertebrally into the first and second dorsal nerves. Within thirty seconds pain had completely ceased. Five minutes later 5 cc. of an 80 per cent solution of alcohol was introduced into each of the two dorsal nerves. The next day he walked 150 yards as fast as he could, and although he became alarmingly cyanotic and dyspneic, he definitely asserted that he had no pain. Since the treatment he has been able to walk about comfortably with almost complete absence of precordial pain. He has had no further attacks of nocturnal pain.

Sensory Findings.—June 11, 1925, before the injection:

A. Epicritic sensibilities.
  1. A zone of hypesthesia extended over the entire left side of the chest both anteriorly and posteriorly.
  2. The patient had great difficulty in discriminating differences of 5 degrees of temperature on the left side both anteriorly and posteriorly.
  3. Cutaneous localization was definitely impaired over the entire left side.

B. Protopathic sensibilities.
  1. An area of hyperalgesia extended over the skin segments supplied by the first and second intercostal nerves on the left side.
  2. A zone of hyperthermalgesia was observed on the left side over the first and second intercostal spaces. The patient found no difficulty in discriminating between extremes of temperature over the hyperirritable zones.

Conclusion.—1. Because of attacks of angina pectoris, the chest of a patient suffering from thrombotic process both in the interbrain and in the coronary arteries was examined by sensory tests, which revealed disturbances in the afferent systems conveying impulses to the thalamus. Nevertheless, a zone of hyperalgesia was found over the skin areas supplied by the first and second intercostal nerves on the left side.

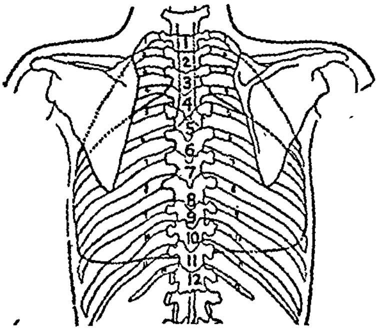

Fig. 4.—Sensory findings before injection.

2. Because of signs pointing to a progression of the thrombotic process in the thalamus, it became quite evident that little information would be obtained by comparing the sensory examination of the chest before injection with that after the injection.

3. No ill effects or complications of any kind following the injections have been observed.

Case 5.—*History.*—N. B., a man, aged 65, suffering from angina pectoris due to coronary sclerosis, had complained of pain over the heart for a period of two years. The pain was chiefly located over the precordium and radiated down the left upper extremity and was described as constricting in nature, and at other times as sticking in type. Often the pain was boring, seeming to penetrate anteroposteriorly. The attacks often occurred two or three times daily. Almost nightly, at about 2 in the morning, he would be awakened by a terrific pain over the precordium, accompanied by a sense of suffocation and a fear of impending death. Venesection was resorted to several times. Morphine relieved him, but amyl nitrite was of little avail. Physical examination showed a greatly enlarged heart with a marked dilatation of the aorta. A paravertebral injection of alcohol was made into the second, third, fourth and fifth dorsal roots, which relieved him of further attacks both day and night. Shortness of breath still persisted on exertion. Since the alcohol injection, the patient has had several attacks of pulmonary edema with absence of pain. Before the treatment was given, these attacks were always accompanied by severe agonizing pain.

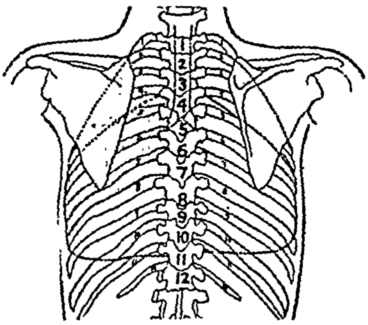

Fig. 5.—Sensory findings before injection.

Sensory Findings.—Sept. 15, 1925, before the injection:

A. Epicritic sensibilities.
  1. A zone of hyperesthesia to cotton wool was found over the skin supplied by the first to the sixth intercostal nerves on the left side.
  2. There was no disturbance in the patient's ability to discriminate temperatures ranging between 20 and 38 C.
  3. Cutaneous localization was well performed.

B. Protopathic sensibilities.
  1. A zone of hyperalgesia extended over the skin supplied by the first to the sixth intercostal nerves on the left side.
  2. There was greatly increased reaction on the left side to temperatures below 20 and above 45 C. He had no difficulty in recognizing these extremes of temperature on the left side.

November 15, sixty days after the injection:

A. Epicritic sensibilities.
  1. There was a marked hypesthesia, which extended over the skin on the left side supplied by the first to the sixth intercostal nerves, respectively. In fact, he hardly perceived the stroking of the cotton wool over the skin.
  2. He was completely unable to discriminate fine differences in temperature; i. e., between 20 and 38 C.
  3. Cutaneous localization was greatly impaired.

B. Protopathic sensibilities.
  1. A zone of hypalgesia practically approaching analgesia extended over the skin segments supplied by the first to the sixth intercostal nerves.
  2. A marked disturbance in his ability to discriminate between extremes of temperature, i. e., below 20 and above 45 C. on the left side, was noted. When the affected area was compared with the right side a definite hypothermalgesia was noted to exist over the former.

Conclusion.—1. Before the injection of alcohol, a zone of hyperirritability existed over the dermatomes supplied by the first to the sixth intercostal nerves. Sixty-one days after the injection, the conducting function of these intercostal nerves was greatly curtailed.

2. There was no return of pain in spite of the continuance of attacks of pulmonary edema. Nov. 19, 1925, he died suddenly during one of these attacks. He had been relieved for a period of nine weeks.

Careful electrocardiographic studies were carried out in detail on all patients before and after treatment both at rest and after exercise. The results are so variable that at present no conclusions can be drawn.

CONCLUSIONS

1. In attempts to relieve angina pectoris by operation, there are dangers and inconsistencies.

2. Five patients were relieved of severe cardiac pain by paravertebral injections of alcohol.

3. The results indicate a new, efficacious, simple and harmless method of alleviating severe cardiac pain.

Gun Hill Road near Jerome Avenue.

Treatment of Tuberculosis.—Open air in the treatment of phthisis should be as complete as possible, and the patient must be inured to it gradually. In particular, it is to be insisted that the patient be exposed to full daylight, unobstructed by glass. This is a very important element in open-air treatment, but sun, unless the air is cold, is safest avoided by patients with active lung disease. A prolonged sunning may lead to undesirable congestion of the tuberculous areas. The effect of open air, and especially of cold air breathed, seems to be a stimulation of metabolism, leading to increased appetite and well being.—Riviere, Clive.

EFFECT OF PARATHYROID HORMONE ON CERTAIN SIGNS AND SYMPTOMS IN TUBERCULOSIS

PRELIMINARY REPORT *

BURGESS GORDON, M.D.
JESSE L. ROARK, M.D.

A. KENNETH LEWIS, M.D.
PHILADELPHIA

There has been much speculation as to the relation of calcium metabolism to the healing of tuberculosis. That some relation exists has naturally been suggested by calcification occurring in healed tuberculous lesions; but that calcium alone has a definite influence is questioned, although it has long been advocated in the treatment of tuberculosis. We have in the use of parathyroid hormone, elaborated by Collip,[1] a means for increasing the amount of calcium in the blood and possibly of affecting the calcium metabolism. The present study is concerned with this effect on lesions, and certain features and complications in tuberculosis.

A series of sixty patients in various stages of tuberculosis has been observed for periods ranging from up to a few days to four or five months. A further number of patients with other forms of pulmonary infection have been included in the study for control purposes. This additional series was utilized as a means for noting changes in special signs and symptoms which could not be clearly differentiated in the tuberculous group. It is not our purpose at this time to give more than a preliminary note on the effect of parathyroid hormone, because the patients have not been followed for a sufficient period of time to justify a final statement. There are a number of observations, however, which seem to warrant this preliminary report. In presenting the data, we realize the difficulty of attributing certain phenomena as due exclusively to the medication. Rest in bed, psychic influences and secondary infections at times confuse the real picture of tuberculosis and give a false impression of the progress of the disease. Symptomatic observations should not be the determining evidence of therapy but only suggestive of it. They are mentioned in this report with this feeling in mind. At the beginning of the investigation, an effort was made to rule out the effect of rest as a factor to the progress of the disease by selecting patients who had been under a routine hospital management for a considerable period without improvement. A small number of patients with acute complications on admission were given treatment without delay.

Objective and subjective observations were made at frequent intervals. The objective findings consisted of roentgen-ray observations, blood calcium and blood clotting determinations, strength tests, and laryngeal examinations with a recording of the weight, temperature, pulse rate and blood pressure. The subjective observations were necessarily limited to symptoms that were recorded daily. To prevent the patients from comparing notes, the studies were carried out in separate groups in which no contact was possible, so that the patients could not suggest improvement to one another. There were no changes made in the diets or in the usual routine of treatment. So far as possible all medication was discontinued, with the exception of parathyroid hormone. Special complications, such as hemorrhage, laryngeal involvement, pleurisy and gastro-intestinal disturbances, were relieved when necessary by the usual measures, but were observed specially for any effect that might be attributed to the parathyroid hormone.[2] The hormone was given subcutaneously; the dosage at the start of the investigation was between 10 and 20 units daily. Later, it was found that certain changes occurred in patients in whom the large dosage was used, and this led to reduced dosage of hormone and a plan of treatment which had to do primarily with the clinical signs rather than with the level of calcium in the blood. The Clark and Collip[3] modification of the Kramer and Tisdall method was used in making the calcium determinations. After the first few injections of hormone, the determinations were made every six or twelve hours. When the calcium level was found fairly constant and there were no clinical signs of hypercalcemia, the estimations were made every six days.

CHANGES NOTED AFTER USE OF PARATHYROID HORMONE

Strength.—It was found that a number of patients showed a striking general increase of strength after the first few injections of parathyroid hormone. The strength of grip, as determined by a dynamometer apparatus, also showed a progressive weekly increase. The strength was maintained more constantly during repeated tests every few minutes than before treatment was instituted. There seemed also to be less tendency for the ambulatory patients to tire under moderate exercise. There were several patients, however, who appeared to lose strength during treatment, the strength being regained following the withdrawal of the medication, or if it was given in smaller dosage. Utilizing this information, a later series of patients was given the hormone in smaller dosage, with less striking but generally more favorable results.

Muscular Pain.—It was observed that pain and cramps in the calves of the legs and in other parts frequently disappeared and did not recur after the first few injections. Arthritic pains were less frequently relieved. In two patients, aching in the knee and elbow joints developed during treatment. These symptoms were attributed to the medication because they ceased after the hormone administration was discontinued.

Warmth.—A subjective feeling of warmth was not uncommon, quite often limited to the feet and legs but also noticed in the face and other parts of the body. There seemed to be some relation between the time of administration and the sensation of warmth, the latter appearing at its height in from two to four hours following the hormone injection, regardless of the time of day. The patients, however, stated that they usually felt warmer at all times than they did before the treatment was instituted.

Respiratory Symptoms.—The changes referable to the respiratory apparatus were numerous and varied

widely in different individuals. However, when present, they occurred with remarkable constancy in relation to the dose of hormone and plan of treatment.

A most common symptom was dryness of the throat, which occurred after a total dosage of from 30 to 40 units of hormone, when the calcium was elevated to 13 or 14 mg. per hundred cubic centimeters of blood. The dryness generally continued until a lower dosage of parathyroid hormone was used and the blood calcium level correspondingly reduced.

In five patients with moderately advanced laryngeal tuberculosis, there was some decrease of pain with less difficulty in swallowing after the first or second week of treatment. In some of these patients, however, who developed dryness of the throat there was later an increase of the pain with dysphagia. These symptoms subsided during a reduced dosage of the hormone, except in two patients in whom it was necessary to discontinue the treatments.

It seemed at first that the patients with a productive cough were definitely relieved during the hormone injections. The amount of expectoration was decreased, and it appeared that the tendency to cough was lessened. As the treatment progressed, however, there were several instances of increased coughing which apparently continued until the dosage of the parathyroid hormone was reduced. The patients with a dry, hacking cough were usually more uncomfortable following the first few injections because of increased coughing and curious tickling sensations in the chest and throat. They seemed to expectorate considerable quantities of mucus, which appeared to originate in the throat. These unpleasant symptoms were usually prevented, and there appeared to be considerable general improvement if less frequent injections and smaller dosage of the hormone were used.

In four patients there was marked relief from attacks of dyspnea soon after the administration of 10 units of hormone. The improvement occurred in the chronic fibroid types of tuberculosis with acute respiratory complications.

Pain in the chest, both of muscular and of pleural origin, was often relieved after the first or second day of treatment. This observation is quite fairly open to criticism, because pain occurs and disappears repeatedly without apparent cause. However, the acute pleurisies seemed to respond far more rapidly after the parathyroid hormone injections than following other measures for the relief of pain. Four patients who had been suffering for several days from extremely painful pleurisy, unrelieved by narcotics in ordinary dosage, showed marked improvement within a few hours after the injection of 10 units of parathyroid hormone. There were other instances with less severe pain, but the results were nevertheless striking.

The observations on the respiratory symptoms emphasize the importance of carefully noting daily changes in the patient's condition. It was possible to increase the comfort of the patient by giving the parathyroid hormone, but if the dosage was excessive, or if the intervals between injections were not sufficiently long, the former symptoms were apt to return quickly with aggravation. The dryness in the throat and irritative coughing were especially characteristic of overdosage.

Gastro-Intestinal Symptoms.—The immediate effect of the parathyroid hormone on gastro-intestinal symptoms was not remarkable. There seemed to be a slight tendency toward constipation, which was marked in two instances. There was generally an improved appetite after the first week of treatment. There was no definite effect on abdominal pain or other discomfort. An insufficient number of patients with intestinal tuberculosis has been followed to warrant a statement on the effect of the hormone in this condition.

Hemoptysis.—In the objective findings, the outstanding clinical observation was the control of pulmonary hemorrhage. It is fully realized that rest in bed and sedatives in the majority of instances control hemoptysis, but there are many patients who do not satisfactorily respond to this form of treatment, and if there is response it is tedious and unreliable. Repeated hemorrhages are common, and there are often long periods of blood spitting. It was the latter group (twenty-four patients), with a history of frequent hemoptysis unrelieved permanently by the usual measures, that was selected for this study. It was the plan in the early work to give sufficient parathyroid hormone to maintain a high blood calcium, but this was modified when it was noted that hemoptysis recurred in three patients, although an elevated calcium level was maintained. In the subsequent treatment of pulmonary hemorrhage less hormone has been used with more satisfactory results. There have been nineteen patients without recurrence in two months. In general, patients with marked hemorrhage have been given from 30 to 40 units of parathyroid hormone in two divided doses during a period of thirty-six hours. This dosage was then followed by injections of 10 units of the hormone every second day for two or three weeks. In the patients with only moderate blood spitting, 10 units of the hormone has been given every third day for five or six doses, when the administration was further reduced. It has been felt that if parathyroid hormone, used according to this plan, does not control pulmonary hemorrhage, it is futile to increase the dosage because the results would probably be unsatisfactory. At present we regard the undesirable patients for treatment as those with hemorrhage due to bronchiectasis and pulmonary abscess, and those with very frank hemorrhage conceivably due to large vessel erosions.

Laryngeal Tuberculosis.—The favorable effect of parathyroid hormone in tuberculous laryngitis was much less constant than the effect on pulmonary hemorrhage. It was noted, however, by Dr. R. M. Lukens that in five patients there was a reduction of the edema and swelling of the arytenoids and glottis during treatment. In one instance there was striking evidence of improvement in the lesion. Dryness of the throat often occurred when a large dosage of the hormone was given. This caused not only a marked aggravation of the local symptoms, but also further changes in the laryngeal structures, apparently because of the increased irritation and cough which the dryness provoked. These changes were usually promptly relieved after discontinuing treatment or reducing the dosage of hormone.

Pleural and Pulmonary Râles.—Five patients with acute pleuritic pain were studied after the injection of parathyroid hormone, and three showed marked decrease of the friction sounds within a few hours after the administration of 15 units of hormone. There was also a striking decrease in the pulmonary râles which occurred during superimposed respiratory infections. It was noticed also in several patients that râles *occurring in active tuberculous processes lessened during treatment.*

Blood Pressure, Temperature and Pulse Rate, and Weight.—The blood pressure (hypotension is commonly found in tuberculous patients) was unaffected by the parathyroid hormone injections. The temperature and pulse have varied apparently only with the activity of the disease. After a period of high and frequent dosage, it was not uncommon for the temperature to show marked evening elevations often accompanied by chills. It cannot be certain that these periods of activity would not have occurred without medication; nevertheless, they were present so often during high dosage of hormone as to suggest that the extract was at least playing a part in the phenomenon. This reaction also occurred in the far advanced cases under comparatively small dosage and has always been the signal to reduce the amount of hormone. At present there seems to be no direct stimulating effect of the hormone on the mechanisms that control the temperature and pulse, but it is possible that the tuberculous process may be affected, which in turn affects the temperature and pulse rate. The gain in weight has varied with the general condition of the patient.

LABORATORY FINDINGS

The routine laboratory procedures have shown in most instances a typical rise in the blood calcium following the injection of from 10 to 20 units of parathyroid hormone. This rise has usually occurred within twelve hours after administration and has shown an increase of 2 or 3 mg. of calcium above the normal level of from 9 to 11 mg. per hundred cubic centimeters of blood. In most patients, it has been possible to maintain a calcium level of between 12 and 14 mg. per hundred cubic centimeters of blood during the daily injection of from 10 to 20 units of hormone. There have been a few instances of irregular response. In two patients a lowered calcium level persisted for several days during the first administration of hormone before an elevation occurred. In other instances there was a transient fall lasting for a few hours after the first administration before a sharp rise in the calcium level to above normal occurred. A transient reduction in the clotting time of the blood (from one to three minutes) has been noted in a few patients during a period when the calcium was first elevated to from 12 to 14 mg. per hundred cubic centimeters of blood. No striking change in the clotting time has been observed when a small dosage of parathyroid hormone has been used.

ROENTGEN-RAY OBSERVATIONS

Roentgenograms made by Dr. J. T. Farrell, Jr., have been essentially negative so far as calcification is concerned. There have been no areas of increased density in the lung fields which can be attributed to a calcifying effect of parathyroid hormone. A number of the patients showed a clearing of the lung fields which seemed to be more rapid than would ordinarily be expected from the usual treatment. However, there were other patients who showed just as striking change in the reverse order. For the present the roentgen-ray observations have not been striking, except for the absence of calcification in patients given hormone daily for a period of three months and in other patients given less intensive treatment for over four months.

COMMENT

In considering the possible value and harmfulness of parathyroid hormone in tuberculosis, it is to be emphasized that the findings are only suggestive. The uncertain nature of the disease requires caution in drawing hasty conclusions. Furthermore, there is no final evidence at this time to justify a single claim for a specific curative effect. The evidence is largely clinical, and therefore must be considered with extreme and careful criticism. It appears that the hormone has a favorable action on certain signs and symptoms, notably cough, dyspnea, hemoptysis, pleurisy and pulmonary congestion. The mechanism for these phenomena is uncertain. It is not unlikely that the improvement is influenced by some change in the utilization of calcium, the result at first being due to a simple dehydration which removes or lessens exudation. This possibility is suggested particularly in the observations on pleurisy and pulmonary congestion in which the râles are reduced during therapy. The reduced clotting time of the blood may have some influence in the control of pulmonary hemorrhage. There may also be an effect of calcium on the plasma membrane or in the blood lymph vessels which results in lessened permeability. Such possibilities are not merely speculative; they are suggested largely through the action attributed to calcium[4] and the knowledge that this important salt is necessary for certain chemical and physiologic activities in the body. The presence of a parathyroid dysfunction in tuberculosis is unproved, but this gland undoubtedly exerts some influence on calcium metabolism. This influence is true also of an active parathyroid hormone. The danger and possible failure in such therapy appears at the onset to be in overdosage by causing an excessive elimination, the formation of certain chemical products, or the disturbance in equilibrium of important mineral salts. A recent editorial in THE JOURNAL[5] calls attention to the possibilities or harm that may be produced by parathyroid hormone. THE JOURNAL refers to the work of Greenwald and Gross,[6] who have demonstrated the behavior of certain salts, particularly their increased excretion, following the use of this hormone. It is a timely warning that a preparation so potent should be used with discrimination. Furthermore, aside from the possible danger from this hormone, there may be a failure to obtain certain favorable effects by overdosage. This failure is emphasized in the treatment of pulmonary hemorrhage in which hemoptysis is controlled during the first hours of therapy, but returns if large dosage of the hormone is continued, although an increased blood calcium level has been maintained. There are no data at this time to suggest that the utilization of calcium depends on an increased amount of calcium in the circulating blood. There is furthermore no suggestion in the roentgen-ray observations to show that calcification depends wholly on an elevated blood calcium. These observations at least favor the impression that overdosage is useless if not actually harmful —harmful, because the normal storage of calcium in the body may be depleted, and areas of disease undergoing repair may also be so affected.

Biol. Chem. **66**: 217 (Nov.) 1925.

A detailed consideration of the prolonged use of parathyroid hormone in tuberculosis is not within the scope of this report, because an insufficient number of patients have been observed for a long period of time. At present, however, it seems that the dosage should be governed largely by the signs and symptoms and the type and extent of the disease. It is obvious for various reasons not to expect a favorable effect in the chronic or actively progressive forms undergoing caseation and cavity formation, except possibly to relieve certain complications. There appears to be a more suitable use in those patients with so-called exudative processes and hemorrhage, pleurisy and associated pulmonary infections. In the selected patients without special features, the most constant improvement has been noted during the administration of from 5 to 15 units of hormone once or twice weekly. This dosage has been supplemented by additional hormone in the treatment of special symptoms or complications. The study has emphasized the importance of noting daily changes in the patient's condition not only because of relief that may be obtained in complications, but also for the prevention of ill effects, especially increased coughing in certain types, dryness of the throat, fever and elevated pulse rate which may occur during overdosage. Care should always be used to prevent overdosage.

SUMMARY

1. To a series of sixty tuberculous patients, parathyroid hormone injections were given to determine the effect on certain signs and symptoms common to this disease.

2. There was improvement in the strength, increased warmth, and lessened muscular and pleuritic pain. In some instances, there was also a favorable effect on laryngeal tuberculosis.

3. The effect on cough was variable; the dry hacking cough was often aggravated; the productive coughs were often less troublesome during treatment, and there was decreased expectoration. There was a favorable effect on dyspnea.

4. The most striking objective feature was in the control of pulmonary hemorrhage. This was relieved quite constantly, according to a plan of treatment outlined. There was also a decrease in the edema of the arytenoids and other structures involved in laryngeal tuberculosis, with some evidence of healing. In pleurisy and pulmonary congestion there was evidence of decreased râles following the administration of the parathyroid hormone.

5. In the roentgen-ray examination, there was a suggestive clearing of the lung fields, but no evidence of calcification.

6. In general there was a favorable effect on the condition of the patients, as shown by increase of appetite, gain in weight, and lowered temperature and pulse rate.

7. The untoward features were arthritic pains, dryness of the throat, increased coughing, palpitation, weakness, and periods of elevated temperature and pulse with loss of weight and appetite, and were usually due to overdosage. These phenomena were generally relieved following the withdrawal of the medication, and seldom reappeared during moderate dosage.

8. There appears to be no evidence that a favorable effect on pulmonary tuberculosis is obtained from maintaining a high calcium content in the circulating blood.

THE FEMALE SEX HORMONE

IV. ITS OCCURRENCE IN THE CIRCULATING AND MENSTRUAL BLOOD OF THE HUMAN FEMALE: PRELIMINARY REPORT *

ROBERT T. FRANK, M.D.
AND
M. A. GOLDBERGER, M.D.
NEW YORK

Independently, and almost simultaneously, Loewe[1] and one of us, together with collaborators[2] demonstrated the presence of the female sex hormone in the circulating blood. This observation is the first demonstration by means of a specific and direct test of the presence of a true hormone in the circulation.

The test employed is the change from leukocytes to squamous epithelium noted in the vaginal smear of castrated rats and mice.[3]

In this short preliminary report, no retails as to method and technic will be given.

We have obtained the female sex hormone from the blood specimens by means of lipoid extraction performed under identical conditions by identical methods. The results are sufficiently concordant to be considered quantitative. Blood has been obtained from thirty-eight patients. In some instances, specimens have been taken at intervals of from five to seven days through two monthly cycles from the same patient.

From our investigation it has become evident that:

1. The amount of female sex hormone found in the circulating blood of the human female varies during the menstrual cycle. An abrupt increase takes place beginning between the tenth to the fifteenth day counted from the first day of the last menstruation.

2. The female sex hormone is present in greatest concentration in the circulating blood near the first day of menstruation.

3. With the onset of menstruation, the female sex hormone abruptly diminishes in the general circulation.

4. The female sex hormone appears in the menstrual blood, there being present in from triple to six fold the concentration found in the circulating blood.

5. In certain types of menorrhagia and metrorrhagia, the female sex hormone may be (*a*) absent from both the circulating and the uterine blood; (*b*) in others, present in both the circulating and the uterine blood.

6. In certain amenorrheas, an increase in amount of the female sex hormone may be demonstrated in the circulating blood.

From these observations we feel justified in concluding that:

(*a*) The female sex hormone secreted by the maturing follicle reaches the general circulation.

(*b*) The sudden increase of female sex hormone found from ten to fifteen days after the last menstruation may be used approximately to determine the time of ovulation.

(*c*) The female sex hormone secreted by the corpus luteum likewise reaches the general circulation, continuing the pregravid stimulation of the genital tract and breasts as demonstrated by other methods in a previous communication.[4]

---

2. Frank, R. T.; Frank, M. L.; Gustavson, R. G., and Weyerts, W. W.: Demonstration of the Female Sex Hormone in the Circulating Blood, I, Preliminary Report, J. A. M. A. **85**: 510 (Aug. 15) 1925.

3. Stockard, C. R., and Papanicolaou, G. N.: The Existence of a Typical Oestrous Cycle in the Guinea-Pig, with a Study of Its Histological and Physiological Changes, Am. J. Anat. **22**: 225 (Sept.) 1917.

(*d*) During the pregravid stage, either (1) a concentration and storage of the female sex hormone takes place in the uterine tissues, or (2) the uterine mucosa at the time of the menses filters out the female sex hormone from the circulating blood.

(*e*) Two types of menorrhagia or metrorrhagia occur, the one with oversecretion, the other with undersecretion of the female sex hormone. Further study may enable us to elaborate proper forms of treatment based on the etiology.

(*f*) Some amenorrheas may be due to persistence of the corpus luteum, as evidenced by a persistence and undue concentration of the female sex hormone in the circulating blood.

These studies are being continued and elaborated with every prospect of affording valuable aid in both diagnosis and therapy.

Clinical Notes, Suggestions and New Instruments

A CASE OF MALTA FEVER *

Henry S. Acken, Jr., M.D., Brooklyn

R. G., a minister, aged 39, admitted to the service of Dr. Kandt, Nov. 30, 1925, complaining of headache over the eyes and soreness of the abdomen of five weeks duration, had been treated at his home in New York State during the previous five weeks. The family and past histories were negative. The illness really began about the first of September, 1925, when the patient began to have a feeling of persistent fatigue and weakness. November 4, he had his first known rise of temperature to 101. This dropped during the following week but rose again on the 9th to 102, when he had a chill and profuse sweat, together with persistent headache and abdominal soreness. A tentative diagnosis of typhoid was made by his family physician, but the Widal test was returned as negative. By November 16, the temperature had reached normal, but a week later the patient was forced to go to bed on account of extreme weakness. November 27, the temperature rose to 103, and he complained of weakness, profuse sweat and chills. He entered the hospital three days later; his temperature on admission was 103.

The patient was large and well proportioned, with no abnormal physical signs except a temperature of 103, flushed face and generalized abdominal tenderness. The spleen was not felt. The systolic blood pressure was 120; diastolic, 78. The blood picture was remarkable only in that the leukocyte count was 8,600, with 60 per cent polymorphonuclear cells and 40 per cent mononuclears. A blood count had been taken at home, November 14, which had shown a leukocyte count of 7,600 with 37 per cent polymorphonuclears, and 59 per cent small and 3 per cent large mononuclear cells. The Wassermann and Widal reactions, stool culture, malarial smear, and roentgenograms of the teeth were all negative; the blood culture was sterile and the urine normal.

During the patient's residence at the hospital, the pulse was never above 108 and respiration never above 25. The temperature came down gradually, reaching normal after six days. Nothing remarkable was noted in the convalescence. December 11, the patient was discharged without diagnosis. His temperature had then been normal for about a week. After his return home he still felt weak and his "nerves were shattered." December 16, his temperature rose to 99 and December 18, it was 103.

The patient was readmitted to the hospital on this date, and the physical findings were as before. The blood picture, however, showed a leukocyte count of 7,000, with 26 per cent polymorphonuclears, and 4 per cent large and 70 per cent small mononuclear cells. It was on this second admission that a tentative diagnosis of Malta fever was made, and the search was started for the organism in the blood stream, but was negative. Jan. 5, 1926, a culture of *Micrococcus melitensis* was obtained through the courtesy of Dr. Chester Keefer of Johns Hopkins Hospital. Prior to this, however, cystoscopy and roentgenograms of the chest and sinuses had all proved negative.

The course was similar to that of the previous admission, and the patient became afebrile after nine days, December 25. However, January 5, an agglutination test was done by Dr. Smith, using the culture of *M. melitensis* and the technic as described by Dr. Keefer. This showed a positive agglutination in dilution of 1:800, while a control serum was entirely negative. Subsequent study of the blood picture showed a gradual increase in the polymorphonuclear count and a decrease in the small mononuclear count, with a practically constant leukocyte count; the blood picture became normal, January 3, The patient was discharged, January 10, slightly weak and nervous, after about seventeen afebrile days. He has remained well since.

SUMMARY

Three known periods of pyrexia (up to 103), characterized by headache, abdominal soreness, weakness, chills and sweats and no joint pains occurred in this patient. The physical findings were negative. The spleen was never palpable. There was a lymphocytosis, with the blood picture gradually returning to normal. Positive agglutination with *M. melitensis* and the closely related *B. abortus* was obtained. Recovery was spontaneous without specific treatment.

CONCLUSION

It may be said that while Malta fever is thought to be restricted to the island which gives it its name and to southern Europe, several cases have been reported that show it to be endemic in the United States. It should be considered and eliminated as a possibility in obscure fevers.

Seventh Avenue and Sixth Street.

INDUSTRIAL POISONING FROM LOW CONCENTRATIONS OF CHLORINE GAS *

Carey P. McCord, M.D., Cincinnati

The recent advocacy of chlorine in the treatment of respiratory infections has tended to create the belief that industrial poisoning from low concentrations of this gas is improbable. The concentration of chlorine recommended for therapeutic purposes approximates 0.015 mg. per liter of air. This concentration is fairly close to that present in the bleach rooms in paper mills, laundries and textile mills. Barring accidents, it is believed that chlorine concentrations in such industries range downward from 0.03 mg. per liter of air. Apart from minor inconveniences, such low concentrations will not produce any acute harmful effects. When, however, exposure is continued over a period of years, an occasional worker may be expected to become severely harmed. Such an instance is cited below.

REPORT OF CASE

History.—L. R., white laborer, began employment in a paper mill in 1920. His work, family and personal history up to that time were without significance. At his place of work it was a trades practice to place many-colored, waste paper stock into tanks, together with a solution of commercial "bleach powder" for the purpose of whitening this paper stock. The bleach powder contained about 35 per cent available chlorine. After the bleach treatment the excess fluid was drained off, and the treated stock was dumped from the tanks into a cellar room. The patient's occupation consisted of digging out this paper stock from the drainer room, loading it on hand trucks and transporting it to another room. According to the patient, an odor of chlorine was present at all times but at certain times appeared to be more concentrated. He knew of no accident that led to gross exposure to chlorine.

[4] Frank, R. T., and Gustavson, R. G.: The Female Sex Hormone and the Gestational Gland, J. A. M. A. 84: 1715-1719 (June 6) 1925.

* From the Medical Service of the Methodist Episcopal Hospital.

* From the Industrial Health Conservancy Laboratories.

In 1924, he first noticed a slight cough, associated with sneezing and burning in the eyes. During this period, there were intervals of a week or two in which he noticed no discomfort. Then the coughing would return for a period of several days. Progressively, the coughing became more severe.

By February, 1925, the condition had become severe, and pain was continuously present in the upper portions of both lungs, but particularly in the right. A bronchitis had developed. During this month and the spring months, the patient consulted his family physician on several occasions. A diagnosis was made of pharyngitis and laryngitis. Although extensive treatment was carried out, no betterment took place. The physician advised discontinuance of work in chlorine. This was not done.

The condition of the patient remained about the same until August, 1925, when it became worse. At that time the patient was dyspneic; he had a feeling of oppression in his chest; the pain in the lungs had increased and the coughing and bronchitis were marked. During September, 1925, he was forced to discontinue work and go to bed. His chief complaints at that time were incessant coughing, severe pain in the chest, sore throat, spitting up blood and the feeling of "a belt around the chest." He was confined to the bed or the room for five weeks. November 9, he attempted some work that did not involve exposure. He has not been able to resume full work up to this time. March 11, 1926, he was referred to us because of shortness of breath, bronchitis, and inability to work. When he entered the room it was obvious that he was dyspneic, undernourished, and suffering from almost continuous coughing

Examination.—The pupils were equal, reacting promptly to light and in accommodation. Ophthalmoscopic examination showed the arteries not contracted, the veins not particularly dilated, and no retinitis or hemorrhages. The teeth were in only fair condition; with marked caries. The gums were retracted from the base of the teeth and the whole picture was one of erosion. The voice was markedly husky. The posterior pharynx and tonsils were clean. The epiglottis was normal and the piriform fossae were clean. The arytenoids and the intra-arytenoid area were red and the membrane thickened, but there was no ulceration. No paralysis of the cords was seen but there was some thickening, without deposits or ulcerations.

The thyroid was just palpable. It is noteworthy that the superficial veins over the thyroid were all distinctly enlarged.

Heart: R. C. D. 3.2 x 9.5 cm. The point of maximum impulse was visible and palpable in the fifth space, 9 cm. to the left. R. S. D. 6 cm. There was no dilatation of the aorta. The first sound was slightly reduplicated at the apex, but there was no definite murmur. At the base the second aortic sound was slightly louder than the second pulmonic, but it was not ringing. The cardiac rate was 100. There was no deficit. The vessel walls were not thickened. The pulse was not of high tension. The systolic blood pressure was 132; diastolic, 80.

Over the upper left lung the note was definitely hyperresonant. It was slightly exaggerated even on the upper right side but not as marked as on the left side. Posteriorly the note was hyperresonant on the right side, especially at the base, and continued clear to the twelfth dorsal spine. Respiratory motility was markedly diminished, not extending more than 1.5 cm. on either side. On auscultation the breath sounds in places were harsh, especially on expiration, but at the bases the sounds were distant. There were occasional dry râles, the picture being that of a low grade bronchitis with emphysema. There were rather more râles anteriorly, especially toward the base, but they were dry. The speaking voice was not changed. The whispering voice was much diminished. At the base posteriorly the whispering voice did not come through. The superficial vessels along the costal margin were distinctly injected, running around the axilla on either side. The liver edge was felt three finger breadths below the costal margin, but the liver dulness above did not begin until below the sixth rib.

Roentgen-ray examination showed an old tuberculosis of the upper right lung, with fibrosis in the upper left lung. There was an old healed cavity in the upper right lung. Marked emphysema of both lower lobes was present. The intracostal spaces were increased, and the density of the lung tissue was definitely diminished throughout the lower lobe of both lungs.

We accept this patient's condition as an occupational disease due to prolonged exposure to low concentrations of chlorine gas arising from work processes.

34 West Seventh Street.

CASE OF LEAD POISONING WITH ONSET SIMULATING TRIGEMINAL NEURALGIA [*]

LEE FOSHAY, M.D., CLEVELAND
Fellow in Medicine, Lakeside Hospital and Western Reserve University School of Medicine

This case is reported because it presented a difficult problem in diagnosis and because the character and sequence of symptoms are considered sufficiently rare to arouse interest.

A Croatian, aged 44, occupied as a general laborer in a nearby shipyard, came to the dispensary, Jan. 13, 1925, for relief from excruciating pains, of three weeks' duration, in the right side of the face. He had been perfectly well until Christmas Day, 1924, when suddenly he experienced in the right side of the face a severe, burning pain. He described this as a "hot, jumping toothache in every tooth in the right side." It lasted all day, with severe acute exacerbations, and was so severe at night that he was unable to sleep. During the night he noticed that he began to have intermittent pains in the right arm, originating in the shoulder and radiating down the posterolateral aspect of the arm as far as the elbow. These pains were not as severe as those in the face. The pains in both regions continued similarly for three weeks. During this interval the patient, thinking it was all due to his teeth, went to the dentist, who had recently filled a few small cavities. One upper molar was considered to be suspicious and was extracted. As this produced no relief, the patient was referred to the hospital.

He said that he did not have any contact with lead but that he did painting jobs at irregular intervals, the last job more than two months before the onset. There had been no injuries or periods of exposure to cold, and no recent infections could be recalled. No additional useful information could be obtained.

The temperature and pulse were normal. Critical examination of the head failed to reveal any source of pain. The skin, eyes and ears were normal. The teeth were clean and in excellent condition. The first upper right molar was missing. There was no lead line, no pus in the nose, and no tenderness over the sinuses. The tonsils appeared normal. Two points of tenderness were found, one just anterior to the right tragus and another over the site of the upper right third molar tooth. Slight tapping of any of the teeth in either jaw on the right side caused severe pain. There was exquisite tenderness over the upper third of the right humerus, especially over the course of the musculospiral nerve. There was no atrophy of the face or arm muscles; no loss of power; no gross sensory changes to light touch, pressure, heat, cold, pain, vibratory or tactile discrimination tests, although there seemed to be some vague quantitative difference between the two sides, and no tenderness over the brachial plexus.

Roentgenograms of the teeth and of the region of the right shoulder joint were normal.

The hemoglobin was 90 per cent (Tallqvist).

The specific gravity of the urine was 1.004; there was no albumin, sugar or sediment.

The patient was given codeine sulphate, 0.015 Gm., acetphenetidin, 0.13 Gm., and acetylsalicylic acid, 0.33 Gm., in capsules, every four hours, for the pain and told to report in one week.

January 20, one week later, the condition was much the same. He still spent a large part of every night walking the floor. Examination showed slight atrophy of the extensor muscles of the right forearm, with preservation of the supinator longus. No loss of power could be detected. There was no apparent atrophy of the right masseter. The character of the atrophy of the right forearm suggested lead neuritis, and the diagnosis was made tentatively in spite of the negative history.

---

[*] From the Department of Medicine of Lakeside Hospital and Western Reserve University School of Medicine.

Blood smears were made and stained at once. These showed large numbers of cells containing the characteristic stippling. In a thin blood film they averaged 4 to 5 to each oil immersion lens field. Almost all the red blood cells showed a moderate achromia of the central area.

A few more pointed questions to the patient brought out the fact that although he had not been painting he had been mixing large amounts of lead paint for other men, using both white and red lead oxides almost daily for the past eight months. He said that he did not know that the pigments were made of lead and had taken no precautions to prevent inhalation of the dust.

The gums still showed no lead line. Although the urine was not analyzed for lead, the true history, the evidence for secondary anemia, the findings of large numbers of stippled cells and the character of the muscular atrophy were considered sufficient to establish the diagnosis of lead poisoning. The patient was instructed to take potassium iodide, 5 grains (0.3 Gm.), twice a day and put at rest for a month.

During the latter part of January he reported having had abdominal cramps on several different days and noted that constipation had gradually come on.

February 4, he was examined in the clinic by Dr. Charles F. Hoover, who noted atrophy of the extensors of the right forearm, with preservation of the supinator longus; slight atrophy of the triceps, supraspinatus and latissimus dorsi on the right side; no involvement of the rhomboids, serrati, deltoids and sternocleidomastoids; slight protrusion of the tongue to the right and fine fibrillary twitchings; teeth and gums clean; no lead line; some subjective qualitative difference in tactile perception between the two sides of the face.

By the middle of February the patient had had pain in the left arm and forearm with atrophy of the abductor indicis of the left hand. The atrophy of the right forearm and hand had increased, but there was no atrophy of the masseters. By the middle of March there was both palpable and visible atrophy of the right masseter. The strength of the right hand and arm was markedly reduced, and there was slight impairment on the left side. There had been no pain for almost a month.

Nov. 24, 1925, there were no neuritic pains, and no colic. The strength of both forearms and of both hands was still subnormal. There was persistent weakness of the extensors of the wrists and fingers, greater in the right side. The right masseter was still smaller than the left. The atrophy of the muscles of the forearms was much less than at the time of the previous visit. It was bilaterally equal and would not readily be noticed. The patient had worked steadily since the first of April and had been comfortable.

In February, 1926, fourteen months after the onset, the patient reported himself perfectly well. He had worked steadily for eleven months and was entirely free from symptoms.

COMMENT

The location of the pain, the patient's description of its character, the homolateral radiation to the arm and the Valleix points of hypersensitivity seemed at first to indicate a diagnosis of tic douloureux of the neuritic type. The entire absence of premonitory symptoms, of vasomotor, secretory and trophic disturbances, and the absence of a tic or other motor phenomena seemed to render such a consideration improbable, but it was not until the characteristic atrophy of the arm appeared that the diagnosis of trigeminal neuralgia finally could be abandoned.

In the literature on lead poisoning there are several reports of cranial nerve palsies due to lead. All of these have been painless pareses or paralyses. I have not been able to find any reference to lead neuritis involving the trigeminal nerve, of either the motor or the sensory divisions.

PECULIAR COMPLICATION OF APPENDICITIS

Richard Terrell Davis, M.D., Warsaw, Va.

In clean appendectomies, a routine investigation of subjacent tissues is strongly urged as the part of wisdom. The following is a case in point:

R. M., a youth, aged 16, whose previous health had been good, was taken suddenly ill early in the morning of Aug. 7, 1925. He evinced severe pain in the abdomen, centering at the umbilicus, together with constant nausea. He attributed his symptoms to having eaten largely of watermelon the evening before. I saw him for the first time at 10:30. His expression was anxious; the abdomen was normal in contour but with some rigidity of both rectus muscles. He complained of pain in the umbilical region, and of tenderness on deep pressure at McBurney's point. He experienced almost equal tenderness slightly above the umbilicus. The temperature was 99.8; pulse, 94; respiration, 22. The heart was normal. The urine had some albumin and a few hyaline and granular casts. The total leukocyte count was 14,000; polymorphonuclears, 93 per cent. The patient was hurried to the hospital, where I operated on him at 2 p. m. A right rectus incision was made and I found a very long, somewhat swollen appendix with a few adhesions, and engorgement of the adjacent mesenteric vessels. The appendix was removed in the usual way.

Its condition, however, did not seem to me sufficiently involved to account for the severity of the patient's symptoms, so I investigated further. At a distance of about 30 cm. from the ileocecal valve, I found on the ileum a Meckel's diverticulum. This diverticulum was 5 cm. long, and 1.8 cm. broad at its base, with a wooden toothpick lying in it parallel to its long axis and perforating its apex; 1.2 cm. of the toothpick extended outside the perforation and impinged on an adjacent coil of intestine, through the serous and muscular coats of which it had cut. I removed the diverticulum with the toothpick in situ, repaired the injury to the adjacent intestine, poured 60 cc. of 0.5 per cent solution of merurochrome-220 soluble into the abdominal cavity, and put in a cigaret drain, which was removed the next day. The patient made an uneventful recovery and left the hospital in eight days.

COMPLETE COURSE OF EVENTS IN FRACTURE OF THE BASE OF THE CRANIUM[*]

E. L. Hanson, M.D., Louisville, Ky.

This case beautifully illustrates the basal syndrome. Within forty-five minutes of admission into the hospital, the patient passed through the complete classic sequence of events for basal fracture.

E. R., a white man, aged 22, well developed and well nourished, was admitted to the hospital as an emergency patient, Jan. 3, 1926, suffering from a scalp laceration above the right ear, sustained as a result of being struck by a street car. On examination, a hemorrhage from the right ear into the nasopharynx was found. The patient was semiconscious; there was emesis of the sanguineous gastric contents; the pulse was 85, respiration 24, but not stertorous, and the pupils in midcontraction, responding well to light. The blood pressure was 130 systolic and 70 diastolic, and there was no motor paralysis present. A lumbar puncture revealed hemorrhagic spinal fluid under moderately elevated pressure.

Within twenty minutes of admission and almost immediately following the lumbar puncture, the patient lapsed into deep coma, from which it was impossible to arouse him; the pulse slowed to 60, respiration became deep and stertorous, the right pupil became dilated and fixed, and the blood pressure was 155 systolic and 25 diastolic.

Ten minutes later the patient developed cyanosis, which gradually deepened; the pulse was only 50; respirations slowed until they assumed the Cheyne-Stokes type, the right pupil remained fixed, while the left was now in middilatation, following in sequence the course of the right; the pulse began to quicken and a spinal puncture showed almost undiluted blood under excessive pressure. A transient spastic left hemiplegia was observed, followed shortly by a spastic diplegia. The respiration at this time consisted of long periods of apnea followed by irregular gasping, during which the patient was completely cyanosed. The pulse became increasingly rapid, passing 160 at one time, after which it became irregular but persisted for five minutes after respiration had entirely ceased. From the time of the second lumbar puncture, the needle was kept intact for continuous drainage, and the head of the bed left radically elevated.

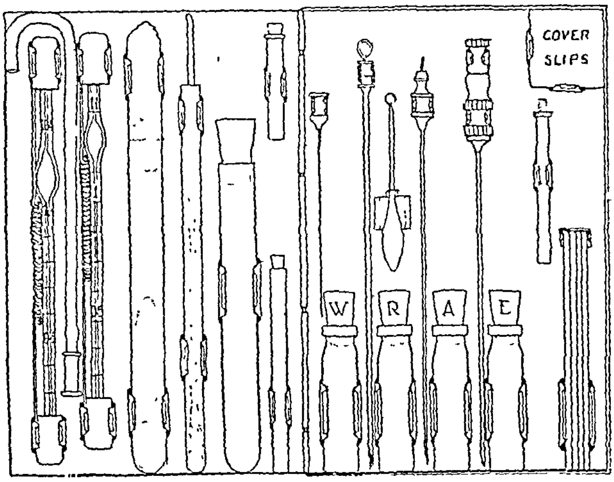
A USEFUL DIAGNOSTIC AID CASE

Harry D. Piercy, M.D., Cleveland

This pocket case contains a number of clinical diagnostic aids that are often required in an emergency and are not as a rule carried in the physician's bag. The delay and inconvenience caused when I have been compelled to return to the office for some of these articles led me to design and make this compact case, which fits into my bag and is always at hand when needed. Its convenience and usefulness has been demonstrated many times, and I feel that it merits this description.

The case, of German silver, is hinged on one side and opens into two halves. It measures 10 by 15 by 3 cm. and weighs, with its contents, about 425 Gm. It contains the pipets for making blood counts; glass cover slips for blood smears; glass slides for blood or pus smears; a blood agar slant with sterile swab; a sterile test tube for blood or other fluid; hypodermic vials, containing, in one, calcium oxylate, and, in the other, sealed capillary tubes for formaldehyde; four 8 cc. glass vials containing, respectively, diluting fluid for white and for red cells, alcohol and ether; several needles for venipuncture and lumbar puncture, and a blood lancet.



Diagnostic aid case.

The cover slips are contained in the small square box seen in the upper right hand corner. The culture tube here illustrated, made by the Digestive Ferments Company of Detroit, happens to be just the proper size to fit into this case. The spring clips securely sealing the ends of the blood pipets are of obviously simple construction and should be obtainable from any supply house. The articles are securely held in place by nickel plated spring clips of phosphor bronze, soldered to the top and bottom of the case.

8314 Euclid Avenue.

Mitral Stenosis in Women.—The occurrence of "pure mitral stenosis" in women who give no history of any illness prior to the development of cardiac symptoms has always been a puzzling fact, and remains so today.—Sir Thomas Horder, *Brit. Med. J.*, April 3, 1926.

TUBE ADMINISTRATION

STOMACH TUBE ADMINISTRATION

Gavage.—In certain diseases and emergencies, feeding and drug administration by stomach or duodenal tube may become necessary. When, for instance, the patient is unconscious, or for one reason or another unwilling or unable to swallow, food as well as medicine may be placed in the stomach by means of a tube, a procedure known as gavage. Under these circumstances, it is usually easier to pass the tube through the nose than through the mouth. It is less apt to enter the trachea, and the mouth does not have to be pried and kept open by instruments. A tube the diameter of a no. 20 French catheter is employed. For infants, a no. 10 catheter suffices. For adults, the tube should be more than 45 cm. long, as, for example, a duodenal tube; and, if difficulty is encountered in its passage, it may be stiffened for introduction by means of a piano wire, which is withdrawn after the tube has reached the stomach. The tube, well lubricated, is slowly passed through the nostril, the patient's breathing being watched for evidence of embarrassment, coughing or choking. Under no circumstances should fluid be introduced into the tube if a respiratory air current can be heard or felt at the end of the tube. It is wise to withdraw, by means of a syringe, a little of the gastric contents to make certain that the tube has reached the stomach. Lavage may often be practiced at this point with advantage, so as to clear the stomach of stagnating food and mucus.

For the introduction of fluid into the stomach, the barrel of a 15 to 20 cc. glass syringe furnishes a readily available funnel that fits these small tubes. As the procedure is unpleasant and somewhat of a strain to the patient, it should be repeated as infrequently as possible. As a rule it is best not to fill the stomach completely, using from 100 to 300 cc. of fluid. Hence only concentrated food, such as cream and eggs, should be used; and a medicament may be added to this, if required.

Lavage.—Though, by gastric irrigation with water, we can secure almost all the effects that may be required from gastric lavage, or washing of the stomach, there are certain conditions when the addition of a medicament to the irrigating fluid may be of advantage. Thus, in extreme gastrectasia with luxurious development of yeasts or sarcinae, better results can probably be obtained by antiseptic irrigation than by the use of plain water. The best fluid for this purpose is a saturated solution of salicylic acid (about 1 : 500), as it combines a high degree of antisepticity with low toxicity; and the slight solubility of salicylic acid in water precludes the use of solutions of excessive strength. While warm alkali irrigation (up to 5 per cent sodium bicarbonate) is probably but little superior to the copious use of plain water in hyperchlorhydria, it is of decided advantage in favoring removal of mucus in gastric catarrh. The most rational method of silver nitrate administration in gastric disease is, no doubt, silver nitrate irrigation practiced according to the method of Gumprecht:[54]

---

* This is the twenty-second of a series of articles on "The Technic of Medication." When completed the articles will be assembled in book form.

> After the stomach has been washed out with water, one introduces from 100 to 200 cc. of 1 to 2 per cent solution of silver nitrate (in distilled water) for one or two minutes and then siphons it out. This is to bind gastric chloride. Now from 100 to 250 cc. of this solution is introduced and permitted to remain for two minutes, then withdrawn, and the stomach is washed with warm water until the fluid—at first cloudy with silver chloride—finally returns clear.

DUODENAL TUBE ADMINISTRATION

For the administration of medicaments unsuitable for injection into the tissues, a method has of late become available, with the development of the duodenal tube, that is of use most especially in cases of uncontrollable vomiting and purging. This method was developed chiefly by Max Einhorn, from whose book[55] the following items of technic are freely quoted:

> The capsule, as well as the lower part of the rubber tube, is moistened with warm water and put into the pharynx of the patient. Then the latter drinks some water, and the instrument thus soon passes into the stomach. To be certain that the capsule did not get stuck in the esophagus, it is well to have the patient shake his abdomen and to aspirate a syringeful of chyme. This can easily be identified as gastric contents. Now we pass a syringeful of water and then one of air through the instrument. The rubber tube is then clamped off and left alone for about one hour. The patient is told not to close his mouth too tightly, so that the tube is not retarded in its wanderings. The patient must also avoid intentional swallowing of the tube. Through the peristalsis of the stomach the capsule is pushed on farther, and usually passes through the pylorus into the duodenum, and later into the beginning of the small intestine. It is best to have the patient read some light literature, in order to divert his attention. After one hour we examine how far the capsule has progressed; if sign III is near the lips (70 cm.) or inside the mouth, we try to aspirate. If the capsule is in the duodenum, we generally obtain a clear, golden yellow or watery liquid of alkaline reaction and somewhat viscid consistency. If, however, it is in the stomach, we obtain an acid liquid resembling the one first removed. This can, of course, occur if the tube lies in the stomach in a coiled manner. Should the latter be the case, we must partly withdraw the tube, after putting water and air through it, up to the mark II (56 cm.). The tube is then again clamped off, and after from one-half to one hour the procedure is repeated. We generally succeed in nearly all cases (of course, not in such where there is pyloric stenosis) in obtaining duodenal contents. When the tube is to be withdrawn, it is clamped and slowly pulled out. When the beginning of the esophagus is reached, the patient is told to swallow, and during this act the capsule is withdrawn.

The tube, stiffened if required by the temporary introduction of piano wire, may also be passed through the nostril, a useful modification of the technic to be resorted to with unconscious or delirious patients, as the tube can thus be passed with much less trouble and the patient might bite the tube passed through the mouth. Passing the tube through the nose is also to be preferred when it is to remain in the duodenum for days.

If there is doubt whether the capsule is in the stomach or in the duodenum, the following hints may be helpful:

> 1. If the capsule is in the stomach and we aspirate, the syringe quickly fills with fluid or air, provided the holes are not clogged by coarse food. The heavier rubber tube attached to the syringe does not collapse, as this organ is always filled with either air or liquid. If, however, the capsule is in the duodenum, one finds that the connecting rubber tube will collapse on rapid aspiration. [After waiting a short while and after trying aspiration, slowly, fluid enters the syringe.]
>
> 2. If the capsule is in the stomach and air is forced through, the patient feels the entrance of the air very plainly and can localize where it occurred. If the capsule is in the duodenum or jejunum, the patient does not usually feel the entrance of air.
>
> 3. *The Milk Test.*—If we give the patient two or three swallows of milk (provided, of course, that no milk has been previously taken), and then aspirate with the capsule in the duodenum, we obtain pure duodenal contents (golden yellow or clear as water) without any admixture of milk. If, however, the capsule is in the stomach, the milk appears at once.
>
> 4. The roentgen rays show the position of the capsule in the stomach or duodenum very plainly.

If the tube, after a sojourn of three hours (or—if it had been introduced the night before at retiring—in the early morning), has not reached the duodenum, the patient is instructed to lie half an hour on his right side. Aspiration is then tried; if gastric contents are obtained, the patient is given something to drink and told to walk about for ten or fifteen minutes. If the examination again shows that the tube is in the stomach, an effervescing drink is given. Half an hour later, aspiration is again performed. Should the tube, showing mark III at the lips, still have failed to enter the duodenum, the patient is given 0.5 mg. of atropine sulphate. One hour later another examination is made. If the tube is still in the stomach, an effervescent drink is given again. After waiting a few hours more and still finding the tube in the stomach, an aperient (magnesium sulphate or citrate) may be employed.

When the duodenal tube is used for alimentation, the food is usually given every two hours, eight feedings a day. The standard food is milk (240 cc.), one raw egg, and a tablespoonful or two of lactose. Should the lactose cause diarrhea, it is omitted. Whatever is fed to the patient should be of blood temperature—neither cold nor hot—and it must be given slowly.

After each feeding, before the stopcock is closed, a little water and then some air should be injected, in order to keep the tube always empty. If one is not careful to clean out the tube each time with water and air, the end of the tube is liable to become clogged in a day or two. Then the tube has to be taken out and replaced, with a great deal of inconvenience to the patient, as well as to the physician and nurse; and the tube removed is often found spoiled. While the patient has the tube in, his mouth should frequently be washed out with some good mouth wash. As these patients do not eat anything, there is nothing to cleanse the surface of the tongue, and it is very essential that it should be kept clean.

Duodenal alimentation may be life saving in the vicious circle of vomiting that has produced starvation acidosis, which in turn maintains the vomiting and may render it quite uncontrollable.

---

[54] Gumprecht, F.: Die Technik der speciellen Therapie, Jena, Gustav Fischer, 1903, p. 95.

[55] Einhorn, Max: The Duodenal Tube and Its Possibilities, Philadelphia, W. B. Saunders Company, 1920.

In thrombo-angiitis obliterans, good results have been obtained from flooding the organism with large quantities of fluid (9 or 10 quarts [liters] daily). As such large quantities of fluid cannot be taken by the patient with impunity in the ordinary way, it is given best, according to Willy Meyer, by duodenal injection. The patient may be given his meals in the ordinary way by mouth. At the same time, he is given about 9 liters of Ringer's solution daily through the duodenal tube, which in one case was left in situ for a period of about four weeks.

Remedies can be injected into the duodenum for two purposes: (1) to exert a therapeutic influence within the duodenum or intestine, or (2) to act in distant localities after absorption from duodenum or intestine of special remedies whose sojourn in or passage through the stomach does not appear desirable.

Strong silver protein (0.5 per cent solution) or mild silver protein (20 per cent solution) may be instilled into the duodenum in quantities of about 15 or 20 cc., or one may introduce silver nitrate, 100 cc. of the strength of 1:20,000 up to 1:1,000, with good results in chronic duodenitis and cholecystitis or duodenal ulcer. Cathartics or sedatives may be given to patients who have the duodenal tube in place, directly into the duodenum with quicker and prompter action than through the stomach. Vermifuge and endamebicidal remedies have been given transduodenally to avoid their effect on the stomach in irritable conditions of this organ.

(To be continued)

RELIGIOUS HEALING

PRELIMINARY REPORT

ALICE E. PAULSEN, Ph.D.
NEW YORK

(Concluded from page 1623)

MODERN MOVEMENTS WITHIN THE CHURCH

CATHOLIC CHURCHES

Healing has always occupied considerable attention in the Roman Catholic church. Many Catholic churches possess relics which are believed to have special healing powers. This may be a piece of bone taken from the body of a saint, as a rule one who is said to have performed miracles of healing during his or her lifetime. The believer may at any time offer prayers to this saint or ask the priest to apply the relic. This is done by touching the afflicted part of the body with the relic (enclosed in a case) and it is believed that healing may thus be accelerated. Some churches hold weekly healing services which are attended by all denominations in great numbers. The particular relics at these churches are believed to have special healing power. It is distinctly understood, however, that the patient should also have medical attention when this should be sought.

Some priests carry a portable relic on their visits to the sick. Many report noticeable improvement following its application. The prayers for the sick offered both at the bedside and in the church are believed to have a direct influence on the patient's welfare, and not infrequently marked improvement occurs after the priest has administered unction.

Another healing ceremony observed in the Catholic church is the novena. This consists of visits to seek help by means of touching a relic once a week for nine consecutive weeks, or daily for nine consecutive days. Following each service the patient is touched with the relic. During the nine weeks or days, he is expected to live an especially devout life and to devote considerable time to meditation and prayer.

Still another and perhaps the most important type of healing in connection with the Roman Catholic church is that accomplished at various shrines. There is, as a rule, some legend connected with the shrine which leads the pilgrim to believe that if he makes a pilgrimage to that particular spot and offers a petition for help, he will be instantaneously healed. The devout Catholic is convinced that these cures, when they occur, as they sometimes do, are miracles accomplished through direct answer to his prayer.

Lourdes in France and St. Anne de Beaupré in Canada are the most famous Catholic shrines. The legend connected with Lourdes is that the Blessed Virgin appeared to a peasant girl in that place and told her that there was a spring in the grotto at her feet which would effect the cure of the physical ills of those who would bathe therein. And it is claimed that what the Virgin said is true. The spring was first established in 1888. From that time on pilgrims have gone to Lourdes in great numbers, figures affirming the number to be about 1,000,000 a year now, some for relief from physical ills, some merely for spiritual uplift, some out of mere curiosity. Though comparatively few are healed, it is estimated that since the discovery of the healing power of this pool of water 4,000 in all have experienced cures. In the chapel at the shrine are crutches and other supports that have been thrown aside by the healed who had no further use for them.

A medical board is maintained at the shrine and every cure is certified by this board. A patient must bring with him from his personal physician documentary evidence of his condition before seeking the cure. It is said that only those patients who bring evidence of having suffered from organic disease are classified as miraculously healed. The *Journal de la grotte* reports each case in detail, and any visiting physician who desires to examine any patient when a cure is reported is privileged to do so.

The procedure at Lourdes is very complex. A long series of preparatory ceremonials and devotions precedes the actual dipping in the pool.

SPECIAL ACTIVITIES IN CHURCHES

Aside from any connection with guilds or organized prayer circles, and the like, many churches have well established health work similar to that in any other field of social service, carried on through medical clinic, visiting nurse, social case worker or other individual agent.

Churches also support convalescent homes, preventoriums and hospitals. They have an interest in various auxiliaries in connection with all sorts of medical work. The Episcopal church, for instance, supports the city mission society, which, among its other activities, has visiting or resident chaplains in forty New York hospitals. Because they are so pressed for time, the work of these men is confined almost entirely to the giving of extreme unction and the services to patients about to undergo surgical operations.

The church has an unusual opportunity to reach a great number of people in its various activities. Few recognize the influence that a large modern church may have in a community. It is estimated that 55,500 people used the Madison Avenue Presbyterian Church House for social and educational activities during the past year. Moreover, 39,161 attended Sunday school, 475 of the enrolled members of which are over 18 years of age. Besides this, 58,000 persons attended public worship on Sundays. The pews are free, and all are welcome. During the year the ministers and other members of the staff made 9,699 visits among members of the congregation. This is mentioned in passing merely to indicate the possibilities of such an organization as a means of spreading knowledge and influencing behavior.

PROBLEM RECOGNIZED BY IMPORTANT CHURCH AGENCIES

Leaders in theological seminaries are interested in this problem because they must educate ministers in the right attitude toward it. For the most part they have taken no definite stand in the matter because its growth has come on them unaware. In general, as expressed by Professor Elliott of Union Theological Seminary, the theologian is not desirous of making religion a healing movement. He does not wish to take up work which the psychotherapist is better able to handle. On the other hand, he wishes to do his part if called on to do so, and especially does he wish to make religion an integral part of every aspect of life, that its unifying influence may work for the betterment of man at all times and that it may lend support especially in time of distress.

As a central agency, including in its membership many different denominations and churches throughout the country, the Federal Council of Churches is continually called on to give advice or to express opinions with regard to all aspects of church work. With the present interest in healing and comparatively little knowledge of it on which to base reliable opinions, it has become a practical necessity for this body to undertake research with regard to it. One of the problems before its research department at the present moment is the relation of religion and health. It is withholding opinion until such research shall have been completed.

PSYCHOLOGIC FACTORS

As we review the methods employed in the types of religious therapy which I have been considering, we are immediately impressed with the rôle allotted to suggestion.

Each system in some way introduces the idea of cure or health after preparing the mind through one means or another to accept it, and the fundamental principle of each system is the assumption that any idea possessing the mind tends to materialize in the body.

This is, indeed, a fundamental law in suggestion; but, happily or unhappily, there are numerous ways in which this tendency may be neutralized long before it actually does materialize in the body. Inhibitory influences either in the mind or in the body must be taken into account.

Now, counteracting ideas are among the most powerful inhibitors. Recognizing this, the faith healer makes his first step the overcoming of whatever inhibiting ideas may be present in the patient's mind. Not until this is accomplished does he advance the suggestion designed to serve his especial purpose.

His method may be a process by which he builds up a system of ideas through discussion, reading, recitation, meditation, concentration, "treatment" or other method of filling the patient's mind with his particular line of thought. By constant repetition alone these ideas may gain precedence over other ideas which he constantly denies or associates in a negative way with the patient's desire—to get well, to be prosperous, to be happy. The new system soon becomes dynamic. Being linked with the patient's desire and attached by a religious setting to an instinctive mechanism, it readily gains possession of the field. Constant consideration of it establishes the ideas involved, just as any other habit becomes established. As long as the patient keeps in practice, it is quite as difficult for him to change his mental attitude as it would be for him to change a motor habit once firmly established.

Thus, in the case of the trained Christian Scientist and other New Thought students, the suggestion that enters into the treatment falls in especially prepared soil. The critical faculties are as effectively controlled as if the patient were hypnotized. One link in the chain of conditions that may inhibit the materialization of the idea in bodily activity is eliminated. Then, too, there is the matter of physical relaxation and the further concentration of attention involved in the conditions under which treatment is given. Even though the proper apperceptive mass has not been built up, his mind would naturally be less resistive under these conditions of control.

In some cases the descriptions given by patients who have undergone treatment at the hands of certain practitioners closely resemble the description of what Braid terms slight hypnosis. "The subjects become more or less lethargic but are conscious of what takes place and suffer no subsequent loss of memory." In some of Braid's experiments, this group comprised about 90 per cent of those who responded to curative suggestions.

Cramping the attention in one way or another is an effective method of producing hypnosis. While the members of these healing cults volubly deny that their work in any way involves hypnotism, they could not fail to note the resemblance were they aware of the facts in the case. Few recognize that there are all stages of subjectivity in hypnotism, and that a person may become as effectively controlled by an idea that has taken full possession of his mind as he may be by the operator in what he readily recognizes as hypnosis.

And so it is with other forms of "treatment." The Divine healer, for instance, prepares the way for his final suggestion by a preparatory discourse and affirmative prayer. He withholds the delivery of his dynamic suggestion until something conveyed to him through his rapport with the patient tells him that the psychologic moment has arrived. The patient at this time may be experiencing such intense emotion as the result of the implicit faith that has been established in his mind, with its resultant expectancy, that he may be completely incapacitated from exercising his critical faculties. It may be that he is in some other state of subjectivity, probably hypnotic; or, if he has come for the relief of some acute distress, such as extreme pain, his attention may be so completely absorbed by his symptoms that he can offer no resistance to the idea now implanted in his mind by the operator. The principle is the same in all cases. Ideas that may counteract the situation are first controlled, and the patient's suggestibility is then further enhanced by the conditions of the treatment.

A similar situation prevails in cases in which cures are effected through relics or devotions at shrines. The long series of preliminary ceremonies establish expectancy, and the final act is consummated at a moment when emotion is at its height or when the patient is otherwise unable to oppose the suggestion.

But there are certain aspects of the situation, especially in the case of the more elaborately organized systems, not so readily discernible on the surface. To appreciate these, we must consider how his experience or how his attention to a system of ideas influences the subject's affective life.

Conveyed to the patient in one way or another are certain fundamental ideas which become so firmly implanted in his mind that they furnish him with convictions beyond all dispute which have a marked emotional effect. These ideas form the nucleus for the belief that God, an all powerful, all knowing, everywhere present beneficent power, or force, actually exists; that this power exists in a given relationship to the individual; that the establishment of such a relationship is natural and normal; that such a relationship, once established, enables him to commune with this power; that in this communion a contact is formed which results in a flow of energy which can produce effects not otherwise attainable.

It is in spite of the shortcomings of some systems, even of recognized theology or institutionalized religion, that this development of what we may term personal religion may take place. The personality of the individual, his other religious experiences, his mental attitude and his life in general, are undoubtedly deciding factors; but stimulus is supplied by the system or the experience through which the fundamental ideas are introduced.

The more earnest followers of any of the typical religious therapeutic cults are unanimous in their declaration that they have been led to a fuller realization of life, and that when they first fully comprehended the meaning of the idea of God involved in the teaching of their leader, everything changed for them. They speak of having developed on the basis of this an indescribable joy and satisfaction, a sense of security not otherwise attainable, and an ability to face life with unbounded courage. The full import of these ideas may burst on the patient in the form of sudden enlightenment as the result of some vital experience that serves to integrate his previous experience, or it may be built up by a more gradual process. Regardless of how he comes into a full realization of their significance, this realization has a distinct influence on his affective life.

The appeal to the ego is tremendous. What could have a more expansive influence on the personality than to believe, without the slightest shadow of doubt that one is essential to the plans of God himself; that one partakes of the qualities of God? Followed to its logical conclusion with regard to disease, if God is omnipotent and man partakes of his qualities, indeed, if God is in man, disease is a very minor matter and can readily be overcome through this power within. And what could be more comforting than to know beyond the possibility of any doubt that one may turn at will to a higher power with absolute assurance that one will be given strength to meet any difficulty that may arise? Those who have attained this belief actually report a sense of security beyond their ability to account for otherwise, and those who have learned to carry on what they term effective communion with whatever power it may be that they recognize actually do report a restoration and a rejuvenation as a result of this communion.

The attainment of these convictions is reported to add new zest to life, to develop confidence, serenity of mind, cheerfulness, and a preponderance of loving affections toward others. Unfortunately, in some cases the latter is not followed to its logical conclusion, and it is entirely just to say that many of the cults fall short in this respect, appearing entirely selfish in their purpose. But even though optimism and cheerfulness are induced in the patient on a more superficial basis, it serves its purpose by raising his morale and directing his attitude toward the difficulties of life.

Particular mental states inherent in the functioning of the religious instinct may be of especial importance in their influence on physical conditions. Dr. William Brown Wilde, reader in mental philosophy in the University of Oxford, is sponsor for the statement, "We can say as a fact that suggestion produces results; that autosuggestion produces more permanent results, and that if genuine faith is aroused the most astounding results of a permanent nature may be produced."

William James, in discussing prayer, writes: "As regards prayer for the sick, if any medical fact can be considered to stand firm it is that in certain environments prayer may contribute to recovery and should be encouraged as a therapeutic measure." He goes into considerable detail to make clear the nature of the mental process involved in prayer:

> Man can learn to transcend those limitations (of finite thought) and draw wisdom and power at will . . . The divine presence is known through experience. The turning to a higher plane is a distinct act of consciousness. It is not a vague twilight or semiconscious experience. It is not an ecstasy, it is not a trance. It is not superconsciousness in the Vedantic sense. It is not due to self hypnotism. It is a perfectly calm, sane, sound, rational common sense shifting of consciousness from phenomena of sense perception to phenomena of seership, from the thought of self to a distinctly higher realm. . . . For example, if the lower self be nervous, anxious, tense, one can in a few moments compel it to be calm. This is not done by a word simply. Again I say it is not hypnotism. It is by the exercise of power. One feels that spirit of peace as definitely as heat is perceived on a hot summer day. The power can be as surely used as the sun's rays can be focused and made to work, to set fire to wood.

It may well be that religious healing makes use of forces not ordinarily recognized. It remains for us to study the nature of these forces, to determine how far they are present in the normal person, how far they may be applied with sanity, and what method of application is most advantageous.

SCOPE AND EVALUATION OF THE WORK

Now, we may ask, What limits do the advocates of the so-called faith cures place on the possibilities of their work? Except as indicated in the case of the more conservative in the theological field, the answer is, theoretically none. In the absence of proper records, we can judge only by verbal testimony, such records in the form of narrative as one hears on every side and the few attempts that have been made at a systematic study. In the course of this limited survey we have heard and read endless testimony on the part of persons who believe that they have been cured of everything from a pain in the heel to cancer. Unbounded health, wealth and happiness may be secured by those methods, according to some who have tried them. Results may be instantaneous, gradual, complete or partial.

Certain New Thought advertisements reproduced below, give an idea of what New Thought proposes to accomplish:

"Financial Problems Solved Through New Thought"; "Rheumatism, Hay-Fever and Business Difficulties

Overcome"; "How New Thought Helped When My Husband Became a Flirt"; "How Constructive Thinking Helped Heal Tuberculosis"; "Replenishing the Nerve Centers"; "How to Heal Your Body and Pocketbook Through Expanding Consciousness"; "How to Be a Genius"; "Curing Epilepsy in Fifteen Minutes."

The psychologist Henry H. Goddard, Ph.D.,[12] reports one of the most systematic studies that has ever been made on this subject. Goddard included in his study more than 1,600 records of individual cures, mainly taken from the Divine healer Dowie's work. About two thirds of these were females, and they ranged in age from 6 to 86 years. The greatest number ranged from 20 to 50 years, and among women the married were about three times as numerous as the unmarried. Further results of Dr. Goddard's study were as follows:

> The duration of the disease from which they were healed varies from a few months to fifty-two years. The average time is about twelve years for each sex. Thirty-three per cent report instantaneous cures, 50 per cent gradual, and 17 per cent reported that they were not yet perfectly healed. It must be noted that while 33 per cent report instantaneous healing, it is clear from their own account that they almost always mean that pain ceased instantly. And it may be mentioned that of all the returns that give data on that point, almost every one shows that pain ceased at the time of prayer.
>
> Again, of the whole number, 76 per cent were treated or prayed with by "Dr." Dowie in person; 7.5 per cent were prayed for by him at a distance; 4.5 per cent were prayed for by Mrs. Dowie; 7.5 per cent were healed in answer to their own prayers or efforts, and 4.5 per cent were healed in answer to prayers of friends.
>
> The number of ailments mentioned in their accounts of themselves varies from one to nine for the males and one to eleven for the females.
>
> The time that had elapsed (at the time the study was made) since the cures varied from a few days to fourteen years. Time required for full recovery may be as much as two months. If longer than that, it seems to be regarded as a failure and is not mentioned.

*Goddard's Classification of Diseases Cured**

	Nervous	Circulatory	Respiratory	Digestive	Contagious	Wounds	Cancer	Rheumatism
Males	20	10	20	15	5	14	5	11
Females	22	14.5	18	16	5	3.5	11.5	9.5

* The figures are in per cents.

Among the remarkable features mentioned may be noted:

> Legs lengthened from 1 to 5 inches; "gained 95 pounds"; hip 2½ inches reduced; fifty-six abscesses cured at one time; deaf and dumb; senseless three weeks; "forty whiskies a day" cure; "wreck physically"; hip disease; goiter; three bullets; fever settled in bones; appendicitis; leg shortened 2 inches; born blind.

The following list of troubles, as stated by the patients themselves, is given:

> Abscess; accident; ague; appendicitis; ankle sprained; asthma; backache; back weak; bad habits; bilious trouble; blindness; blind from birth; blood poisoning; Bright's disease; bronchitis; bronchial disease; broken arm; burns; burned hands; blood disease; brain fever; cancer; cancer in tongue; cancerous tumor; carbuncle; catarrh; chills; cholera infantum; cholera morbus; congestion of lungs; consumption; constipation; convulsions; cough; chlorosis; compound curvature of the spine; croup; deafness; deaf and dumb; diabetes; diarrhea; diphtheria; dislocated shoulder; dislocated knee; dropsy; dysentery; dyspepsia; diphtheritic paralysis; devil cast out; earache; eczema; epilepsy; erysipelas; eyes, inflammation of; eyes, weak; eyes, sight failing; feebleminded child; fever; fever sores; felon; fistula; gangrene; gambling; goiter; granulated eyelids; gallstones; headache; healed when dying; heart disease; heart broken; heel lame; hay-fever; hydatids; hydrophobia; hemorrhage of lungs; hemorrhage of kidneys; hemorrhoids; hernia; hip broken; hip disease; hip joint renewed; hysteria; imperfect sight; infidelity; impediment in speech; impotent; indigestion; inflammation of bowels; inflammation of stomach; inflammation of lungs; inflammatory rheumatism; internal tumor; ivy poison; internal troubles; intestinal trouble; insanity; kidney and bladder; knee injured; knee, stiff; knee, swelling in; la grippe; lame, leg too long; leg too short; leg poisoned; leukemia; liver trouble; locomotor ataxia; lung trouble; lung fever; lumbago; malaria, measles; meningitis; morphine habit; mumps; near-sightedness; nervous exhaustion, nervous prostration; nervous trouble; neuralgia; nervous debility; ovarian tumor; palsy; paralysis; periostitis; piles; pneumonia; polypus; puerperal convulsions; peritonitis; pleurisy; paralysis of bowels; palpitations of heart; quinsy; rheumatism, running sore; rib broken; rupture; salt rheum; scalding; scarlet fever; scrofula; skin eruption; skull fracture; sick headache; spasms; seasickness; sleeplessness; smallpox; spinal meningitis; sore throat; spinal disease; spine, curvature of; sciatica; stone cancer; stigmatism; stiff hip joint; stomach trouble; sunstroke; synovitis; symmetrical keratiases of the palms and soles; tapeworm; throat trouble; tobacco; toothache; tonsillitis; tuberculosis; telegraphers' paralysis; tuberculosis of bowels; tumor; tumor, fibroid; thigh bone diseased; typhoid fever; ulcers; urinary trouble; ulcers in bowels; varicose ulcer; varicose veins; whisky; wounds; wrist sprained; weak lungs; weak eyes; white diphtheria; wild hairs; whooping cough; yellow fever.

Similar lists might be prepared from the records of cures ascribed to any one of these systems. We would also find cases of the same nature in which cures failed to be effected. But our research under the present circumstances would do us little good as far as obtaining any real knowledge with regard to the validity of the claims is concerned. This is due to the fact that none of these workers keep adequate records. They depend largely on the patients' testimony for diagnosis as well as for evidence of cure. With no control to determine how many patients were actually suffering from the conditions reported or how many of the reported cures were spontaneous or due to other influences than the mental treatment, we have no way of judging whether its representations are based on pure chance results or on demonstrated efficacy. We have also no data that would definitely warrant either a wholesale or a restricted use of the method in general, although it is obvious that many persons believe that they were cured of diverse diseases, and certain phenomena actually have occurred.

On the surface it would appear that it can do no real harm so long as it remains within rational limits; but it is also obvious that when it is carried into absurdities, as is frequently the case, it can become very dangerous. It is remarkable that the entire matter should be so loosely controlled. To place emphasis on the mental side of life is most important; and, when this emphasis includes a sound philosophy and application of common sense, its contribution can hardly be overestimated. But when it results in the promiscuous teaching and practicing of mental tricks and self delusion, it is a positive menace. To disguise such practice in the name of religion or of science as a means of capitalizing the credulity of the ignorant is despicable.

---

[12] Goddard, H. H.: The Effect of Mind on Body as Evidenced in Faith Cures, Am. J. Psychology **10**: 431 ff.

The newer movements within the church are in the same position as are the older movements independently organized. We can pass no judgment on them except from a theoretical point of view until some effort at a reliable evaluation of their work has been made. A similar statement applies also to the more general uses of religion as a therapeutic or reconstructive agent. With so many other factors involved, without controlled experimentation, judgment can be based only on opinion which is far from conclusive evidence.

Few workers in the religious field are aware of the nature of the problem with which they are dealing. This is quite natural, in view of its complexity. The physician would be at as great a disadvantage in the theological field. Knowing so little about medical science, it is not surprising that they are led astray by apparent similarities in their own teachings and those of the other field. The naive Christian Scientist, for instance, might think that Mrs. Eddy's statement that poison has a harmful effect on the body only because every one believes that it will do harm is fully vindicated by the following report, which recently appeared in the New York *Times:*

> Stockholm, January 18.—By means of hypnotic suggestion, which made subjects believe that poisons administered to them were nothing but water, Dr. Henry Marcus and Dr. Ernst Sahlgren, Stockholm scientists, have been able to offset to a marked degree the effect of poisons on the human system. This was done in a series of experiments at the Karlclinska Medical Institute to determine the effect of hypnotism on organic diseases. The scientists put three subjects into hypnotic sleep and then administered drugs, carefully recording the effects on blood pressure and pulse both with and without suggestion. When a drug which acts to increase blood pressure was administered without suggestion, the blood pressure readings ranged between 109 and 130 and pulse readings from 54 to 100. With suggestion, the blood pressures were from 107 to 116 and pulse readings all less than 67.

Those who advocate religious therapy will do well to compare their methods with other methods which are similar, but which leave out the religious element for good reasons. In this connection, it is interesting to consider the results obtained through various systems of moralization and reeducation used in the practice of psychiatry. Another system in which religion is purposely eliminated is in Coué's method of autosuggestion, which the religionists have so thoroughly embraced.

Some interesting data are being compiled by Dr. Shaler Lawton and his co-workers at the Columbia University College of Physicians and Surgeons. The results of Dr. Lawton's study may well serve as a warning. He is satisfactorily demonstrating, with certain cases for which medicine can do little, that the patient by exercising his morale may so completely control his attention that instead of fixating it on his symptoms, though they are of the most distressing nature, he believes himself cured and becomes entirely unaware of the fact that his physicial condition remains the same and that his disease is running the natural course of its development. The religious healer, misled by the patient's controlled reaction to his symptoms, may be misleading him to let treatment effective in the earlier stages of the disease pass by until it is too late to help him. On the other hand, we must not overlook the fact that we may be considering an efficient method in the course of evolution, and that trial and error may naturally play an important rôle in its progress.

What this method will finally prove to be can be only a matter of conjecture until the situation has been subjected to more intelligent study. In all probability we shall find that there are indeed certain fundamental principles common to all aspects of the situation, but that they will have to be applied in a great variety of ways.

With so many varieties of human personality, the prerequisite state of mind that is essential to the operation of any method can probably be obtained only through a method of approach suitable to the individual make-up and background. This may be strictly religious in some cases, purely ethical in others, and entirely intellectual in others, while certain individuals of weak emotionalism may be susceptible to the influence of any strong or persistent appeal. If the basic principle is faith in the particular appeal of whatever form and the expectancy that develops, similar results are to be expected from widely differing methods adapted to the particular type of individual.

A broad appreciation of the situation would admit that perhaps no one method, whether religious or otherwise, can be expected to reach all types. It may very well be, however, that the religious appeal based on the functioning of an instinctive mechanism is calculated to affect the largest number of persons, and that it may afford the soundest basis for the expectation of lasting results.

The medical profession has largely ignored and even denied the possibility of this method of approach. Meanwhile, as a reaction against the empiric method and the one-time drastic recourse to drugs, there has developed in some quarters considerable "therapeutic nihilism" except for the comparatively few diseases known by modern science to be susceptible to specific therapy. Still, the present materialistic trend tends too much to discredit methods of psychologic appeal to the alleviation of symptoms and cure of disease. This may be because, in spite of the strong evidence that there is some relationship between mind and body, very little is actually known as to how close this relationship is, how this action takes place, and what its limitations are. But it cannot be overemphasized that the physician should take account of whatever influence there may be between mind and body. Much medical practice has admittedly a bad psychologic effect on the patient. Too little effort, for instance, is made to overcome the tendency to concentrate on symptoms of disease and to give the patient an intelligent grasp of the situation that confronts him. Some physicians will send the patient away with a theory or explanation of his disease not founded on any scientific data, which frequently creates or strengthens an attitude of apprehension and makes for continued invalidism or physical and mental ineffectiveness.

Psychologically speaking, certain physicians thus persistently apply the principle of negative suggestion in conditions in which it may produce real untoward effects. This is quite as true of many practices in psychotherapy as it is of minor material or physical therapeutic methods. The medical profession is largely culpable for the widespread rebellion against such methods, as evidenced by the enormous development of these various forms of faith healing.

The medical problem is to discover the underlying facts and principles and to inculcate those which are sound in a well grounded system of practice which will recognize the true function of the mental and the spiritual as well as the material in the alleviation of human ills. Only in this way will it be possible to confine the practice of these methods to those who can be depended on to use them with the unselfish motives characteristic of the best types of religious and medical practice.

SUMMARY

1. The prevalence of religious healing and allied cults bears witness to the fact that the maintenance of individual health has become strongly associated in the minds of many people with religious and metaphysical ideas.

2. There is a great variety of sects and cults and movements appealing to this popular tendency to associate health and religion, such as Christian Science, Jewish Science, Divine Science or Divine Healing, New Thought and Scientific Christianity. These are organized outside the church. In addition, there is considerable activity with regard to healing among Theosophists and Spiritualists. Moreover, the work has also been taken up in the orthodox churches, especially in the Episcopal church. The Nazarene movement makes its appeal through the Episcopal church. The Guild of Health confines its work to other Protestant churches. The novena, the application of relics and visits to shrines, such as Lourdes and St. Anne de Beaupré, are well established practices in the Roman Catholic church. Individual clergy and laymen are also engaged in the work.

3. Some of these agencies are but little organized and have an ephemeral prosperity; but there are some that are well organized and with strong indications of being permanent. Christian Science especially has grown steadily since it originated in 1870, and New Thought has a similar history. The Nazarene movement and the Guild of Health have made a strong appeal within the church.

4. It is impossible to make any close estimate of the total number of adherents of this general movement, since some of the cults do not keep records of their membership. The number of Christian Scientists is estimated at 1,500,000. "Unity," a New Thought cult teaching "Scientific Christianity," is said to reach from three to five million people annually through its publications, lectures and prayer services. The Nazarene movement now has about 7,000 members. If the children and other dependents of adherents to these movements are counted, the number may reach 10,000,000. A wide appeal is also made through magazines and books. Some leaders make use of the radio to broadcast their teachings.

5. The attitude toward the medical profession ranges all the way from hearty cooperation, as in the case of certain individual workers and in some church agencies, to frank hostility, as in the case of Christian Science.

6. Enthusiastic testimonials and the apparently stable membership of some of these organizations (such as Christian Science, Unity and other New Thought cults, also the Nazarene movement and Guild of Health) show that many persons believe themselves to derive great benefit from them. It should be acknowledged that, although some of their practices appear unscientifice and even bizarre, others must be recognized as of possible benefit under certain circumstances.

7. The leaders of these movements either outside or inside the church are little disposed to set any definite limitations to the power and effectiveness of their therapy. The nature of the problem with which they are dealing is not fully comprehended by any of them.

8. Christian Science makes its approach through the concept that disease is "error," New Thought through the immanence of God, and others through still other metaphysical theories on which they base their practice; but practice itself shows considerable uniformity for all of these cults. It seeks to induce a cheerful, confident, serene state of mind, to remove the attitude of invalidism and similar negative emotions and beliefs, to promote relaxation, and to give full play to the suggestion or autosuggestion of health. Various subjective mental states and religious ecstasy are more or less prominent in the treatment of patients.

9. Those resorting to religious and metaphysical healers often express dissatisfaction with physicians for a lack of sympathy and a tendency to build up an attitude of invalidism. Unless the physician is on his guard against giving negative suggestion, such an attitude can very easily be generated in the patient. Leaders of these cults use this as a strong argument against the medical profession.

10. Since religious healing has for the most part been carried on without expert diagnoses of the cases undergoing treatment and without expert determination of their condition after treatment, it is not possible to pass judgment on the merits, harmfulness or limitations of this movement. Where spiritual therapy has been attempted under medical control, the results seem to indicate that:

(*a*) Neurotic patients, alcoholic habitués, drug addicts and the like are sometimes improved by the treatment.

(*b*) The morale and comfort of a patient with organic disease may be improved, while the disease continues to run its course.

There is no way of evaluating the results obtained through religious healing as compared with those obtained with the same types of patients through nonreligious suggestion. Controlled experiments are needed to obtain further data as a basis for judgment of the comparative efficacy of such treatment. Studies of suggestion of a nonreligious nature as a therapeutic agent show that it is quite possible to teach the patient so to control his attention that he is able largely to ignore his symptoms.

11. A scientific study should sharply distinguish between the practice and the theories advanced by these various cults. Probably more attention should be accorded to the practice than to the theory. The theory is perhaps considered necessary as a means of getting hold of the patient, and this no doubt varies to a certain extent. Different persons require different "theories" or modes of approach. The question arises whether or not a scientifically sound basis could be formulated for whatever is useful in these practices, so that the essence of the practice (so far as it may be found good) might be employed with good conscience in treating the sick.

12. Further study should deal with the following problems:

(*a*) What is the common essential of these various practices?

(*b*) How can this essence be given a form and rationale suited to scientific use?

(*c*) What are the benefits, limitations and dangers of these practices as established by a careful try-out under controlled conditions, carried on by physicians in cooperation with interested clergymen?

13. An adequate study will involve much work extended over a long period of time and carried on under unquestioned auspices by a most carefully selected personnel.

14. The whole problem is a serious one which the medical profession should not ignore.

THE HUMORAL MECHANISM AND HORMONE OF EXTERNAL PANCREATIC SECRETION

The remarkable secretory responses that can be secured through stimulation of certain nerves that supply the salivary glands are among the classic demonstrations of experimental physiology. Interruption of the nervous paths, either mechanically or through the action of drugs, is promptly followed by cessation of the characteristic function. Such observations have doubtless been responsible to a considerable degree for the widespread assumption that secretion in general occurs primarily in response to excitation of active cells through nervous paths. In recent years, however, evidence has accumulated to indicate that the promotion of secretory activity can be secured through the blood channels as well as the extrinsic nerves. This is currently described as the humoral, in contrast with the nervous, secretory mechanism.

Ivy and Farrell[1] recently demonstrated that a gastric pouch can be transplanted extra-abdominally into the mammary gland after severance of all nervous connections of the stomach fragment. Such transplants exhibit motility in unison with that of the unharmed gastric residual organ; and they also can secrete an acid juice after a meal or the administration of a secretagogic substance such as histamine. Comparable transplants of pancreatic tissue behave in an analogous secretory manner. According to Ivy,[2] the fact that they secrete continuously, being excited to greatly augmented pancreatic juice output after a meal, definitely establishes a humoral mechanism for pancreatic secretion; for one could scarcely expect the severed nerves to establish their connections in the midst of the far away mammary gland. Ivy and Farrell[3] have also provided what they regard as unequivocal proof that a hormone is concerned in the genesis of the external secretion of the pancreas. When both the pancreas and an independent loop of jejunum were transplanted, thus severing the nervous connections of each, the pancreas transplant secreted copiously after application of dilute hydrochloric acid to the mucosa of the intestinal transplant. Several minutes elapse before the response is secured; how else can it have been attained except through the transport of some newly generated or liberated substance carried by the circulation to its locus of action?

It is not easy to understand why the somewhat comparable salivary and pancreatic glands should behave so differently. Perhaps the correct explanation was ventured long ago by Starling.[4] Commenting on the insignificant secretory response of the pancreas to nervous stimulation, he remarked that whereas in the mouth the reaction, which must be rapid, is entirely nervous, in the stomach there is a mixture of the nervous mechanism with the more primitive chemical mechanism. The nervous secretion preponderates in this viscus. When we come to the pancreas, the primitive chemical mechanism, namely, the formation of hormones and their circulation through the blood to the reactive tissue, suffices to account for the whole activity of the gland, and it is doubtful whether in this activity the nervous system plays any part whatever.

ACIDIFIED MILKS

The action of hydrochloric acid in the process of digestion is largely, if not entirely, due to the number of free hydrogen ions present. Various foods, especially milk, have the property of binding large amounts of acid and converting the hydrogen into a nonionized form, thus to all intents and purposes neutralizing the acid. When foods of the type mentioned are given, much of the hydrochloric acid secreted is rendered inactive. Substances that thus reduce the hydrogen ion concentration are commonly termed "buffers." It has been demonstrated that the buffer value of cow's milk is considerably greater than that of human milk. Therefore the former neutralizes a larger amount of the hydrochloric acid of the stomach secretion. The resultant effect is an interference with the activity of the gastric enzymes through a reduction of the gastric acidity below the optimal hydrogen ion concentration zone of p_H 3.5 to 5.0. By the addition of an acid to cow's milk, its excess buffer salts may be counteracted and its digestibility made to simulate more nearly that of human milk. This method does not entail any appreciable reduction of the food elements, as pertains to the ordinary method of simple dilution.

Along with the demonstration and realization of these facts has come the practice of employing bacterially soured milks and also "debuffering" cow's milk with acid for use in clinical pediatrics. It is based on the assumption that the excess of buffers in cow's milk delays, and in many cases prevents, the completion of gastric digestion in infancy by inhibiting the acidity necessary to the optimal efficiency of the gastric enzymes. Particular emphasis is laid on the importance of gastric lipase. According to Faber, the principle that acidified milk favors the splitting of fats in the stomach may be used in the treatment of various disorders of digestion, particularly intolerance to fat and to sugar. In the latter case an increased digestion of fats appears largely to compensate for the necessary reduction in sugars. A recent writer[1] summarized the present situation in the remark that the rationale of adding an acid to cow's milk to improve its digestibility has been demonstrated by Clark[2] and Faber,[3] and popularized by Marriott.[4] The old fashioned recommendation of additions of lime water has accordingly fallen into disuse, for they are destined to increase the difficulties of gastric digestion at times when this alimentary function may already be under severe stress. Milk modified by the addition of acid has advantages, over bacterially soured milk, of convenience in preparation.

[4] Starling, E. H.: Recent Advances in the Physiology of Digestion, Chicago, W. T. Keener & Co., 1906.

To decrease the digestive burden on the stomach in infants of lessened gastric digestive capacity, acidification of milk may be accomplished in this artificial way by the addition of various acids. Hydrochloric acid, lactic acid, citric acid in the form of lemon juice, and acetic acid as vinegar have all found champions, the choice apparently having been determined by considerations of immediate convenience. The lactic acid procedure has perhaps the greatest vogue at the moment. Partially debuffered milk has a practically unaltered taste and therefore is freely taken without objection by infants who dislike highly acid products. The organic acids mentioned are readily burned in the organism; hence, in contrast with the mineral acid, they function ultimately as potential bases in the metabolism.

There is always danger that a successful therapeutic measure may find application beyond its actual indications. A warning has lately been sounded by Faber[5] of the Stanford University Medical School, who advances the thesis that, on the basis of the available studies, acidified milk may be considered a useful therapeutic agent for certain specific disorders. As such, however, it should be given only when there are specific indications, and for periods of time limited by the regression of symptoms. Organic as well as inorganic acids deflect metabolism from the normal to a recognizable, though not as yet fully determined, extent. For this reason, Faber believes, the routine use of sour milk in the feeding of normal infants is not to be encouraged. For them, modification of cow's milk by dilution and carbohydrate addition remains the method of choice. The clinician should learn the main indications for the use of the acidified products and "play safe" by limiting his prescriptions to them.

LIGHT AND THE EFFECTS OF VITAMIN A

The beneficial effects of sunlight on the human organism have received a significant interpretation through the more recent studies of nutrition. The discovery that rickets represents a true deficiency disorder, and that it can be cured or averted by definite vitamin-bearing foods and certain types of radiant energy alike, has directed attention to the newly recognized potencies of both vitamins and light. Cod liver oil and egg yolk contain antirachitic material. They also furnish liberal amounts of vitamin A, which prevents keratinization of various groups of epithelial cells in the body, of which xerophthalmia is the classic experimental indication. Students in this field of study have already insisted that antiophthalmic and antirachitic potencies should not be regarded as in any sense identical, even though certain food products embody both of them. To emphasize the distinctions, the two properties have already been given separate designations as vitamins A and D, respectively. Thus, cod liver oil and egg yolk contain both; milk fat is comparatively rich in vitamin A and poor in the D factor; and this seems to be true of many "green" foods.

These assertions are based on animal experimentation; nevertheless it has not yet been easy to eradicate the assumption that ultraviolet radiations will replace vitamin A as well as the antirachitic factor. Since deficiency of vitamin A, as exemplified by the characteristic symptom xerophthalmia, has not been extensively encountered in the clinics of this country, there has been little opportunity to test the possible efficacy of light. Recently Bloch[1] of Copenhagen, who has been a pioneer in the study of the xerophthalmias of childhood, has taken occasion to investigate the question in suitable cases. His careful studies indicate that exposure either to the carbon arc light or to sunlight does not cure xerophthalmia. Light cannot replace vitamin A or supply it to the animal organism. Enthusiasm for the benefits of radiant energy and the outdoor life should not, therefore, warrant any one in overlooking the ever present need of vitamin A. Light is not a universal panacea for all human ills. Specific food needs must also be met by any program of physiologic welfare.

---

[1] Bloch, C. E.: Light and the A-Body, Am. J. Dis. Child. **31**: 315 (March) 1926.

The public is becoming increasingly familiar with the immunity gained toward certain microbic diseases by a course of prophylactic treatment. Protection thus secured has become popular and is freely welcomed. Parents and children alike even exhibit eagerness to acquire the obvious advantages. Unlike such immunities, the protection gained at any time through diet against the deficiency disorders represented by lack of vitamins is far less persistent. Consequently, prophylactic measures should not be abandoned when relief seems assured. Bloch has cited illustrations of the wisdom of this advice in connection with the supply of vitamin A; and Hess[2] has lately issued a similar warning in relation to rickets. He points out that recurrences are very frequent, especially during the second year of life. This being the case, it is clear that specific therapy—whether with cod liver oil or ultraviolet irradiation—should be continued after all signs and symptoms of rickets have disappeared. Furthermore, cod liver oil should be given not only during the first, but also during the second winter. This is advisable particularly in regard to infants who have had rickets and who are, therefore, susceptible to a recurrence in the course of the subsequent winter. The mention of the season has reference, of course, to the periods of greatest incidence of the malady.

EUTHENICS

It has been argued that "the accomplishment of a true eugenic program will be the crowning work of the health movement and the grandest service of science to the human race." But present woes demand consideration while we are contemplating future joys. The consequences of innumerable past events press on us; we must try to offset the discomfort or damage of "the heavy hand of the past" and likewise of the ever present menaces of the present. Furthermore—and this is less often adequately emphasized—we must attempt to capitalize omnipresent advantageous possibilities for the future, when opportunity knocks at the door. In matters of health this is sometimes described as an interest in hygiene, the discipline that teaches how to create for ourselves healthful conditions of living. However, human welfare contrasted, perhaps, with mere bodily well being involves a larger objective than individual or public health. It is not merely concerned with curative and preventive medicine; there is the added duty of man to better his conditions by availing himself of added knowledge already at hand. With this in mind, Ellen H. Richards selected the expression "euthenics" to describe "the betterment of living conditions, through conscious endeavor, for the purpose of securing efficient human beings." As a recent writer has added, this does not refer to the efficiency of the factory, which makes a man into a machine to turn out a specific product in the shortest possible time, but the efficiency of the thoroughly sound, highly trained mind in the thoroughly sound, highly trained body, which can accomplish the routine tasks of every day with the minimum of time and effort, leaving over a great store of energy for the additional duties and pleasures of an abundant life.

The contemplation of these purposes through academic training is by no means new. For many years the so-called home economics movement in this country has been concerned with varied aspects of the inclusive problem of how to live. At first the more purely material aspects of the subject—problems of food, clothing and shelter—were most stressed, until the training has extended its ramifications into the curriculums for women in all the state universities. There are indications that even the more conservative colleges for women are contemplating the transfer of emphasis in part from the subject to the object of study. Thus, Vassar College has lately given recognition to eugenics as a field for major study.[1] Properly enough, this has not called for new subjects of instruction, but rather a selection of topics with some motivation of interest in them; physiology, psychology, economics, political science, and even botany and zoology may contribute to the end. It already appears that the most popular combination for a "euthenics major" is that dealing with child welfare, for which the most important courses are child hygiene, child psychology, chemistry of food and nutrition, heredity, charities and corrections, and the family. In every case the courses chosen must have a common focus and must be preceded by training in the elementary sciences, with special emphasis on the general principles of physiology, psychology and economics.

There is no unanimity of opinion with respect to the principles of education. The stress on "practical" or "applied" courses will be debated by many with the contention that apprenticeship in everyday life affords the best training in vocational directions. It is a fact, however, that the traditional curriculum for women is changing. The growing power of women in the field of child health, child protection and child education must be recognized. Eugenics is supplementing hygiene. Professor Cockerell[2] has recently made a plea for something more than mere direct utilitarian concern with the resources about us:

> Is our great undertaking to include simply the sources of food or shelter or clothing? Or if we include the flowers, is it only because they can be eaten by cows, or because innocent people will sometimes buy them, and so give them commercial status? I do not so understand it. We live in a great and wonderful environment, to which we may react in a thousand ways. Broadly speaking, happiness comes through the harmonious exercise of our faculties. To be blind where we might see, callous where we might feel, dumb where we might speak—these are the great futilities, in the presence

of which material wealth is of small account. Thus we must hold that our resources are only limited to those things which we can appreciate with our senses, and get some good by so doing. Wealth of this kind is so abundant that there is more than enough for all. No one can use more than a small part of it, but many minds and hearts, with a common purpose, may approach a grand synthesis which some genius will clarify and define. This is the manner of intellectual progress.

Current Comment

FREAK MEDICAL PATENTS

At various times THE JOURNAL has called attention to the fact that the United States Patent Office is, apparently, unaware that there is such a thing as modern medical knowledge. An article in a current magazine[1] details a number of patents that have been issued for bizarre products and devices of a medical or a medicinal nature. These include Perkins Tractors, Sanche's Oxydonor, the tapeworm trap of Meyers, the "consumption cure" of Serghison, and several others. A patent issued March 1, 1921, to one Mary McGuire Wilson for the "Process of and Material for Reducing Fatty Tissue" could well have been added to the list. According to the patent specifications (no. 1369997), the Wilson formula for reducing weight is: alum, 12 ounces, camphor, 2 ounces; alcohol, 12 fluidounces, and witch hazel, 32 fluidounces. This mixture—which the United States Patent Office considers a new and useful invention—is to be applied to the skin of the "stylish stout" immediately following a hot tub. The stuff is then "whipped or spanked with the fingers to drive the solution into the pores." After this the skin is rolled and another application is made and duly "spanked" in. This is described in the patent specifications as a "process of reducing fatty tissue." Finally the body is sponged with water, to remove any alum that may remain on the skin. Mary McGuire Wilson was granted not only a product patent on her mixture of alum, camphor, alcohol and witch hazel, but also a process patent for applying this ridiculous piece of hokum. Will the patent office never grow up, medically speaking?

A GOVERNOR AND MEDICAL PRACTICE

When the governor of the state of New York signed the Webb-Loomis bill, May 17, he issued an announcement to the voters of the state explaining his action. In that announcement, the governor pointed out that he had had the subject under consideration since the fall of 1924, and that in the interest of the public health he had continuously urged the enactment of legislation which would rid New York of illegal practitioners. An explanation of the Webb-Loomis bill appeared in our columns a few weeks ago. In his discussion of its stipulations, the governor emphasizes particularly the annual registration of all practitioners, the opportunity afforded through a grievance committee for the profession to clean its own house, the provision for prosecution by the attorney-general of all violations of the law, the establishment of minimum requirements for those practicing physiotherapy, and regulation of the use of the title "doctor." Of the latter, the governor said:

> I regard it as highly important that the ignorant and the unthinking be not misguided by the use of the title "Doctor" because it presupposes in the minds of a great many people a knowledge of the human anatomy sufficient to enable the holder of such title to diagnose and prescribe for all the ills the human body is heir to. The title "Doctor" should be made by law to mean what the great majority of people believe it means, and it should not be promiscuously bestowed upon individuals so lacking in proper qualification as to be unable to tell the difference between indigestion and hydrophobia. There is no function of government to my mind more important than the preservation of the public health.

SYPHILITIC INFECTION FROM THE CADAVER

Through long custom, one is apt to forget the dangers attendant on certain occupations and to neglect the precautions that should be taken in connection with them. It may therefore be timely to call the attention of physicians, pathologists and others who have occasion to handle cadavers to the possibility of contracting syphilis in this manner. There has been some doubt concerning the possibility of infection from the bodies of persons dying of syphilis, and the tendency exists to regard the matter lightly. The report of a number of instances and the results of recent experiments indicate, however, that the danger is actual. Erich Hoffmann[1] recently collected from the literature reports of nine certain and seven probable cases of syphilis contracted from cadavers. Since many such accidents would probably be kept secret, or at least not published, this must be far less than the actual number. He found that postmortem multiplication of spirochetes takes place not only in macerated fetuses and in the bodies of infants with congenital syphilis, but also in bodies of adults and of rabbits infected with syphilis. Motility of the organisms is retained for from twenty-four to thirty-six hours, and form and staining reactions for many days. Their virulence apparently lasts at least twenty-four hours, and Koch reported the infection of a rabbit with tissues taken from a cadaver three days after death. A few years ago, Kratzeisen[2] investigated the viability of spirochetes from six syphilitic cadavers. He found that spirochetes kept in various fluids, including water, serum and bile, multiplied for from twelve to twenty-four hours. In most cases they showed beginning degeneration only after twenty-four hours, and complete destruction at the end of seventy-two hours. They lived longest in bile, so that one would expect infection to take place most readily from the liver. From these results it would appear easy for one, in performing a necropsy on a syphilitic cadaver, to contract the infection through a scratch or abrasion in the skin.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

Personal.—Dr. George E. Blue, Montgomery, was elected president of the Alabama Power Company Surgeons at the annual meeting, May 12, to succeed Dr. Aaron L. Harlan, Alexander City; Dr. Samuel R. Benedict, Birmingham, the chief surgeon, was presented with a watch by other members at this meeting.

ARKANSAS

Hospital News.—The new building for advanced cases of tuberculosis to replace the building recently destroyed by fire at the Arkansas Tuberculosis Sanatorium will be completed in June——A building being erected by the Ancient Order of United Workmen of Arkansas which will be donated to the state for a general hospital, will be ready for occupancy in July.

State Medical Election.—At the annual meeting of the Arkansas Medical Society, Hot Springs National Park, May 18-20, Dr. James M. Lemons, Pine Bluff, was elected president; Dr. Henry Thibault, Scott, president-elect; Drs. Grayson E. Tarkington, Hot Springs National Park, Thomas F. Kittrell, Texarkana, and James H. Fowler, Harrison, vice presidents; Dr. Royal J. Calcote, Little Rock, treasurer, reelected, and Dr. William R. Bathurst, secretary-editor, Little Rock, reelected. The next annual meeting will be in Little Rock.

CALIFORNIA

L. T. A. Hotten Given Two Years.—The founder of the so-called U. S. Charity Anti-Cancer League, Dr. Lewis T. A. Hotten, who was recently convicted on a narcotic charge, was sentenced, March 29, to two years in the federal prison. The records of the state board of medical examiners show, it is reported, that Hotten's name used to be Hottendorf.

Dr. Bloomfield Appointed Professor of Medicine.—Dr. Arthur L. Bloomfield, associate professor of medicine, Johns Hopkins University Medical School, Baltimore, has been appointed professor of medicine at Stanford University Medical School, San Francisco, beginning with the year 1926-1927 Dr. Bloomfield graduated from the medical department of Johns Hopkins in 1911, and has been connected with the faculty of his alma mater since 1912.

Society News.—A recent meeting of the Alameda County Medical Society was devoted to a symposium on smallpox; Dr. Newton E. Wayson, San Francisco, discussed "Epidemiology of Smallpox"; Dr. Arthur A. O'Neill, San Francisco, "Diagnosis and Treatment of Severe Smallpox"; Dr. John N. Force, Berkeley, "Administrative Application of Intradermal Methods of Vaccination."——The Women Physicians Club of San Francisco, which was recently inaugurated, now has ninety-three members, and under the guidance of its president, Dr. Louise B. Deal, joined the California Federation of Women's Clubs.—Dr. Harold Brunn, professor of surgery, University of California Medical School, addressed the San Joaquin Medical Society, April 1, on "Lung Surgery."

CONNECTICUT

Personal.—Dr. Charles G. Rankin has been appointed health officer of Glastonbury to succeed Dr. Theodore B. Ackerly.——Dr. Alfred J. Finn has been the acting health officer of Waterbury since the death of Dr. Thomas J. Kilmartin.——Dr. Howard D. F. Lockwood has been appointed health officer of Meriden to succeed Dr. Joseph A. Cooke.

Conference on Social Work.—Dr. Alice Hamilton, professor of industrial medicine, Harvard University School of Public Health, addressed the recent Connecticut Conference of Social Work, which was held at Norwich. Among the other speakers were Dr. Elton Mayo, formerly of Australia, now of the University of Pennsylvania, Philadelphia, and George W. Kirchwey, LL.D., New York.

Bulletin on Rabies.—The state department of health issued a bulletin, May 10, in which it is said that for the ten months ending April 30 the department laboratories examined seventy-five heads of animals, of which thirty-one were positive for rabies. This constitutes more examinations than has been made for a similar period in any of the preceding seven fiscal years. The bulletin also notes the precautions that should be taken to avoid exposure to rabies.

GEORGIA

University News.—Mr. A. S. Bourne, Augusta and New York, has donated to the department of internal medicine of the University of Georgia School of Medicine $5,000, which will be used for the purchase of equipment.

Personal.—Dr. Hudnall G. Weaver is serving as temporary health officer of Macon, pending the selection of a successor to Dr. Charles L. Ridley, who resigned, May 1, to become medical director of the Bankers' Health and Life Insurance Company.——Dr. William C. Humphries, Acworth, who has been appointed health officer for the city of Griffin and Spalding County, will take up his new duties, June 1.

Medical Moral Turpitude.—In a recent decision, the Supreme Court of Georgia upheld the state board of medical examiners in revoking the licenses of Drs. N. A. and T. W. Hughes, Atlanta. The court said in part that the legislature may enact that one who has been convicted of crime "involving moral turpitude" should no longer practice medicine. It was pointed out that the act of 1918 declares that a licentiate's name be removed from the records in the office of any clerk of court, and his license revoked on the ground of conviction of crime involving moral turpitude. The Hughes cases were appealed from the Fulton Superior Court, which had upheld the state board of medical examiners in revoking the licenses of Drs. N. A. and T. W. Hughes, Oct. 9, 1924, the charges by the board in each case having been, first, advertising to treat venereal diseases, and, secondly, having been convicted and sentenced in federal court in Dallas, Texas, in 1914 for using the mails for fraudulent purposes.

ILLINOIS

Naprapaths Arrested.—Perley W. Johnson and William Sandell, naprapaths of Barrington, were arrested, April 16, it is reported, on a state warrant charging them with practicing medicine without a license; they were released under $2,500 bonds.

Personal.—Dr. Cyrus H. Anderson, formerly superintendent of the Illinois State Hospital at Anna, assumed charge of the state hospital at Watertown, May 15, succeeding Dr. Joseph H. Ellingsworth, who was transferred to the state institution at Alton.——Dr. Glenn J. Tygett has resigned as city health officer of Anna and accepted a position on the staff of the Anna State Hospital.——Dr. Bellenden S. Hutcheson has been reappointed health officer of Cairo.

Hospital News.—The new Madison County Sanitarium at Edwardsville was formally opened to the public, May 7.——The new U. S. Veterans' Bureau Hospital, erected at Five Points, North Chicago, for the care of mentally ill veterans, was dedicated with appropriate ceremonies, May 15. Among the speakers at the ceremonies were Gen. Frank T. Hines, Washington, D. C., director of the Veterans' Bureau; Mr. Scott W. Lucas, commander of the American Legion, Department of Illinois, and other distinguished civilians.——Springfield's new $100,000 contagious disease hospital was opened, May 13.

Chicago

Rush Alumni Clinics.—Rush Medical College will conduct, June 14-18, a clinic week for the benefit of its alumni, which will become an annual event if it proves of general interest. Members of the faculty have heartily responded to the plan, and suggestions from the alumni, addressed to Rush Medical College, Harrison and Wood streets, will be appreciated. The annual faculty and alumni dinner will be at the Auditorium Hotel, June 15, 7 p. m. Among other reunions, the 1916 class will hold its tenth anniversary at this time.

Conference on Tuberculosis.—Special features at the Mississippi Valley Conference on Tuberculosis, Chicago, June 14-16, Edgewater Beach Hotel, will be the annual banquet, a child health education luncheon, a seal sale conference, and a secretaries' luncheon; among the topics for discussion will be the education of the layman, after-care and employment of the tuberculous, chest surgery, and tuberculosis in industry. Dr. Linsly R. Williams of the National Tuberculosis Association; Charles E. A. Winslow, Dr.P.H., president American Public Health Association; Dr. James A. Britton, Chicago; Dr. Anthony J. Lanza, New York; Drs. John M. Dodson, Frank L. Rector and Morris Fishbein, all of Chicago, will address the conference.

Society News.—Dr. Carl Beck addressed the Chicago Medical Society, May 26, on "Medicine in Europe."——The annual meeting of the Chicago Neurological Society was held at the new prison at Statesville, May 22; among others, Dr. Sanger Brown, president, gave an historical sketch of the society; the scientific program was in charge of Dr. Herman M. Adler and his assistants.——Dr. Agnes V. Fuller addressed the Chicago Council of Medical Women, May 25, on "Cesarean Section."——At the recent annual meeting of the Chicago Tuberculosis Society, Dr. Henry C. Sweany was elected president; Dr. Hiram H. Bay, vice president, and Dr. Walter H. Watterson, Maywood, secretary.——Dr. Edward S. Blaine has been elected president of the Chicago Roentgen Society; Dr. Walter T. Bronson, vice president, and Dr. Robert A. Arens, secretary-treasurer.

KANSAS

State Medical Election.—At the annual meeting of the Kansas Medical Society, Kansas City, May 4-6, Dr. Francis A. Carmichael, Osawatomie, was elected president; Dr. Benjamin F. Morgan, Clay Center, president-elect; Drs. Earle G. Brown, Topeka, Ivan B. Parker, Hill City, and Jonathan B. Carter, Wilson, vice presidents; Dr. John F. Hassig, Kansas City, secretary, and Dr. George M. Gray, Kansas City, treasurer.

Personal.—Dr. Roland G. Breuer has resigned as assistant superintendent of the Kansas State Tuberculosis Sanatorium at Norton to accept a position in Cincinnati as medical director of a pharmaceutical company.——Gerald W. Smith, Pittsburg, Kan., and Fred E. Angle, Kansas City, members of the senior class at the University of Kansas School of Medicine, have received appointments as assistant surgeons, lieutenant, junior grade, in the U. S. Navy Medical Department, and will report for duty, July 1; the appointments followed examinations held, January 4, at Great Lakes Naval Training Station, Ill.

Society Bestows Gold-Headed Cane.—The Rice County Medical Society celebrated the fiftieth anniversary of the graduation in medicine of Dr. Powhatan P. Trueheart at a dinner in Sterling, March 25, and commemorated the event by presenting to the guest of honor a gold-headed cane, bearing the inscription "1876-1926 Dr. P. P. Trueheart. From Rice County Medical Society." Dr. Trueheart spoke on "Then and Now," to which Drs. Charles E. Fisher and Horace G. Welsch and Mr. W. B. Wirshing responded; six physicians who began the study of medicine in Dr. Trueheart's office were assigned to speak on "One of His Boys." All members of the society were present except two, who were unavoidably absent.

MAINE

State Medical Meeting.—The seventy-fourth annual meeting of the Maine Medical Association will be at Poland Springs, June 10-12, under the presidency of Dr. Joseph D. Phillips, Southwest Harbor. The house of delegates will meet Thursday, 7:30 p. m., at the Riccar Inn, and the council at the close of the meeting of the house of delegates. Dr. Wendell C. Phillips, New York, President of the American Medical Association, will deliver the address at the banquet, Thursday evening; other visiting speakers will be Dr. John B. Deaver, Philadelphia, "Surgical versus Medical Treatment of Gallbladder Diseases"; Dr. Joseph Muir, New York, "Radiotherapy of Cancer of the Uterine Cervix," and Dr. Fred J. Tees, Montreal, "Treatment of Some of the Commoner Fractures." There will be a symposium on obstetrics, Saturday morning, by Drs. Leonard H. Ford, Bangor; Harold W. Garcelon, Auburn; Adam P. Leighton, Jr., Portland; Ralph L. Reynolds, Waterville, and Foster S. Kellogg, Boston. Entertainment has been provided for the ladies, and a golf tournament arranged for Saturday afternoon.

MASSACHUSETTS

Hospital News.—The new St. Luke's Hospital, Pittsfield, was formally opened, April 18, under the management of the Sisters of Providence. The hospital is five stories high with a complete hospital unit on each of the four upper floors. There are seventy-five private rooms, eight small wards, and ten rooms of two beds each. When fully completed, the investment will represent about a half million dollars.

Society News.—Dr. Milton C. Winternitz, dean, Yale University Medical School, New Haven, Conn., addressed the Fall River Medical Society, April 8, at its annual dinner on "Recent Advances and Studies in the Pathology of the Cardiovascular System," illustrated by photomicrographs.——Dr. George F. MacKay, Dalton, has been elected president of the Berkshire District Medical Society, and Dr. A. C. Smith, president of the Plymouth District Medical Society.

Study of Tropical Diseases.——The *Boston Globe*, May 14, announces that Dr. Richard P. Strong, professor of tropical medicine, Harvard University Medical School, will lead an expedition to Liberia next month, for the purpose of studying tropical diseases and the effects of certain remedies on them. Other members of the party will be Dr. George C. Shattuck, Joseph Bequaert, Ph.D., and Glover M. Allen, Ph.D., secretary, Boston Society of Natural History. Max Theiler, also a botanist, a photographer and a zoologist, will be in the party.

State Medical Meeting.—The one hundred and forty-fifth annual meeting of the Massachusetts Medical Society will be held at the Hotel Kimball, Springfield, June 8-9, under the presidency of Dr. James S. Stone, Boston. The secretaries of the district medical societies will have a luncheon at 1 p. m., Tuesday, and various scientific sections will meet at 2 p. m. There will be a symposium on peptic ulcer in the section on surgery, in which Drs. Charles L. Connor, Boston, Ernest L. Davis, Springfield, Frank H. Lahey and Franklin W. White, both of Boston, Albert A. Berg, New York, and Charles H. Mayo, Rochester, Minn., will take part. Among others, Drs. James A. Miller, New York, and Wyman Whittemore, Boston, will address the section on tuberculosis, and Dr. Leo V. Friedman, Boston, and George W. Kosmak, New York, the section on obstetrics and gynecology; Tuesday evening, Dr. William Darrach, New York, will deliver the Shattuck lecture, his subject being "The Interrelations of the Physician and the Hospital." The section on medicine which meets Wednesday morning at 9 o'clock will be addressed by Drs. Charles H. Lawrence, Jr., Boston; Burton E. Hamilton, Boston, and Henry S. Plummer, Rochester, Minn. Among others, Dr. Donald S. King, Boston, will address the section on pediatrics on "The Relation of the School Physician to the Family Doctor," and Dr. Edwin T. Wyman, Boston, the section on radiology and physiotherapy on "Clinical Application of Ultraviolet Rays." Dr. Charles F. Painter, Newton, will deliver the annual discourse, Wednesday afternoon on "Educational Requirements for Twentieth Century Practice: Who Should Determine Them and How They May Be Best Achieved?" The annual dinner will also be Wednesday afternoon, and on Wednesday morning a "college town" automobile trip for ladies to Mount Holyoke, Amherst, Massachusetts Agricultural and Smith colleges.

MINNESOTA

University News.—Dr. Leon Velasco Blanco of the University of Buenos Aires visited the University of Minnesota in April to arrange for an exchange of professors of the medical schools of the two universities for next year.

Dr. Taylor Honored.—The Minnesota Trudeau Medical Society gave an anniversary dinner at the Masonic Temple, St. Paul, May 17, in honor of Dr. Henry Longstreet Taylor, and to commemorate his founding the first permanent tuberculosis sanatorium in the state. Dr. Arthur A. Sweeney was toastmaster, and the speakers were Dr. Robinson Bosworth, superintendent, Municipal Sanatorium, Rockford, Ill., and Dr. Pearl M. Hall, superintendent, Minnesota State Sanatorium, Ah-gwah-ching. Dr. Taylor has been engaged in antituberculosis work since 1893; he opened the Pokegama Sanatorium, the first permanent institution for the treatment of tuberculosis in Minnesota, in 1905; he was elected president of the Minnesota Public Health Association in 1924, and a vice president of the National Tuberculosis Association in 1925.

MONTANA

State Medical Meeting.—The annual meeting of the Montana Medical Association will be at Billings, July 16-17, following the meeting of the Montana Health Association, July 14-15, and that of the Montana Academy of Oto-Ophthalmology; among the visiting speakers will be Drs. William J. Mayo, Rochester, Minn.; Lawrence Webster Fox, Philadelphia; Morris Fishbein and Henry Schmitz, both of Chicago; Frederick M. Allen, Morristown, N. J., and Arthur D. Dunn, of the University of Nebraska. Entertainment has been arranged to include golfing, fishing, swimming and trips to the mountains for those who remain over Sunday, the eighteenth.

Rocky Mountain Spotted Fever.—There had been twelve cases of spotted fever this season reported to the state board of health up to May 12, a smaller number than usual. A fatal case was reported as occurring in Mineral County, and was the first case ever reported as occurring there. Three cases occurred in Ravalli County, with one death: the two patients that recovered had each had one dose of vaccine; two fatal cases occurred in Missoula County; two cases were reported from the vicinity of Malta, two in Garfield and one each in Golden Valley and in Wheatland County. The vaccine developed by Drs. Spencer and Parker, working for the U. S. Public Health Service in cooperation with the state board of entomology, is not yet available for general distribution, but more than 500 people in the Bitter Root Valley have been vaccinated this year. The state board requests physicians to report promptly any cases coming under their observation.

NEW YORK

Hospital News.—Governor Smith signed an act, May 6, appropriating $12,500,000 for the improvement of state hospitals; this money will be taken from the $50,000,000 hospital bond issue; a similar sum was appropriated last year.

Mental Clinic.—Dr. George W. Goler, city health officer, Rochester, announces that a city mental clinic will be started, September 1, in cooperation with the University of Rochester School of Medicine. The schools and various other organizations are requested to send "problem cases" to the clinic.

Personal.—Rowan Whealdon, field secretary of the Oregon Tuberculosis Association, has been appointed executive secretary of the Cattaraugus County Tuberculosis and Public Health Association to succeed John Armstrong, who has been promoted to director, Bureau of Health Education of the Cattaraugus County Department of Health.

Health at Albany.—Telegraphic returns from sixty-nine cities with a total population of about 29,000,000 for the week ending May 8 indicates that the highest mortality rate (22.6) was for Albany, and that the mortality rate for the group of cities was 14.5. For the corresponding week last year the mortality rate for Albany was 16.4, and for the group of cities, 13.3.

New York City

Society News.—Dr. George E. Brewer addressed the West Side Clinical Society, May 13, on "Military Surgery."——Drs. Readie G. Snyder and Solomon Fineman will address the Medical Society of the County of New York, May 24, at the Academy of Medicine on "A Clinical and X-Ray Study of High Colonic Irrigations in the Therapy of Subacute and Chronic Arthritis."

Promotions at Columbia University.—Nicholas Murray Butler, president of Columbia University, announced, May 9, says the New York *Times*, the following promotions on the faculty of the College of Physicians and Surgeons: Drs. Louis Bauman, Henry T. Chickering, Robert L. Levy and I. Ogden Woodruff to be assistant professors of clinical medicine; Drs. George C. Andrews, Jr., and Abernethy Benson Cannon, to be assistant professors of dermatology; Dr. Hugh Auchincloss, to be professor of clinical surgery; Dr. William C. Clarke, professor of experimental surgery; Dr. Fordyce B. St. John, professor of surgery, and Dr. George M. MacKenzie, to be associate professor of medicine.

Promotions at Post-Graduate School.—At the recent annual meeting of the faculty of the New York Post-Graduate Medical School and Hospital, the following promotions were announced:

Dr. James L. Joughin, professor, department of neurology.
John A. Killian (Ph.D.), professor of biochemistry, department of laboratories.
Dr. Michael Osnato, professor, department of neurology.
Dr. John D. Stewart, professor of rectal diseases, department of surgery.
Dr. M. Uribe Troncoso, professor, department of ophthalmology.
Dr. Marvin F. Jones, associate professor, department of otology.
Dr. Jerome Selinger, associate professor, department of surgery.
Dr. Dudley D. Stetson, associate professor, department of dermatology.
Dr. Adolph Jacoby, assistant professor, department of gynecology.
Dr. Roy D. Duckworth, assistant professor, department of roentgenology.
Otto Glasser (Ph.D.), assistant professor of biophysics, department of roentgenology.

Tuberculosis Dispensaries.—Thirty-one tuberculosis clinics are included in the Association of Tuberculosis Clinics of the City of New York; nineteen of them are maintained by the city, four by the department of Bellevue and Allied Hospitals, and eight by various other hospitals, and the Brooklyn Tuberculosis Committee. At the recent annual meeting of the association, it was announced that 40,973 persons were examined during 1925, and of these 11,210 were found to be tuberculous. The clinics were instrumental in placing in hospitals and sanatoriums 2,755 patients, or 35 per cent of all the tuberculosis cases disposed of during the year. The visiting nurses of the clinic staffs cover every part of the city. There were 20,840 new patients admitted to the clinics in 1925. Dr. Louis I. Harris, health commissioner, was elected president of the tuberculosis clinics for 1926, and Dr. Max Taschman, vice president.

NORTH CAROLINA

Dean Kitchin Resigns.—Dr. Thurman D. Kitchin, since 1917 professor of physiology and pharmacology, and since 1919 dean at the Wake Forest College School of Medicine, Wake Forest, has tendered his resignation to the board of trustees, effective at the close of the present term. Dean Kitchin plans to return to his former home, Scotland Neck, to resume the practice of medicine.

Anti-Evolution League.—The North Carolina Anti-Evolution League has been chartered by the secretary of state with the avowed purpose of creating public sentiment which will prevent the teaching in schools of the state supported by public taxation of any theory of the origin of man which conflicts with the views of the members of the league; to promote its purposes, the league expects to raise $50,000.

Society News.—Prof. L. H. Snyder of the State College at Raleigh, who was guest of honor at a banquet given by the Wayne County Medical Society, Goldsboro, April 2, gave an address on "Human Blood Groups: Their Inheritance and Racial Significance."——Among the speakers at the May 11 meeting of the Sixth District Medical Society, Wake Forest, were Dr. Stuart McGuire, Richmond, Va., and William L. Poteat, president of Wake Forest College, who spoke on "The Trend of Modern Scientific Methods and Their Influence on Thought." Dr. Thurman D. Kitchin, Wake Forest was elected president of the society, and Dr. Burton W. Fassett, secretary.——At the semiannual meeting of the Tenth District Medical Society, Waynesville, May 5, Dr. Emanuel Libman, New York, gave an address; Dr. Watson S. Rankin, Charlotte, spoke on "The Need for Community Hospitals and the Aid to Be Given Free Beds by the Duke Endowment."——Dr. Andrew J. Crowell, Charlotte, addressed the New York Academy of Medicine, May 23, on "The Curve of Phthalein Excretion: Its Interpretation and Clinical Use." ——Dr. Paul D. White, Boston, recently addressed the Mecklenburg County Medical Society, and was guest of honor at a dinner given by former fellow officers in the A. E. F.——Dr. Paul H. Ringer, Asheville, addressed the congregation of the Old Calvary Episcopal Church, Sunday, May 16, on "What Has Medicine to Do with Religion?"

OHIO

Summer Courses.—The University of Cincinnati College of Medicine announces that its summer courses will open, June 14, and continue for eight weeks; the courses to be given are biochemistry, physiology and bacteriology; all of them are of regular university grade, and full college credit will be given for the number of hours officially published with the course.

State Medical Election.—At the annual meeting of the Ohio State Medical Association, Toledo, May 11-13, Dr. Leora G. Bowers, Dayton, was elected president; Dr. Leslie L. Bigelow, Columbus, president elect; Dr. Herbert M. Platter, Columbus, treasurer, and Mr. Don K. Martin, Columbus, executive secretary, 131 East State Street, Columbus.

Classes for Crippled Children.—Twenty-one cities in Ohio have special classes for crippled children. According to the Ohio Society for Crippled Children, Ohio leads other states in home instruction, furnished for children who cannot be transported to the special classes. While New York has a larger number of classes for crippled children (114), 105 of them are located in New York City, and the only cities having such classes are Buffalo, Rochester and Binghamton; private agencies in New York maintain special classes in five other cities.

Personal.—Dr. William G. Rhoten, Logan Health Officer, Hocking County, has resigned, effective, June 1, to become the health officer of Wooster and Wayne County.——Dr. Robert H. Riley, assistant director, State Department of Health of Maryland, spent some time in Columbus investigating health administration in Ohio.——Dr. John P. Spooner, Toledo, recently presented thirty bound volumes of The Journal of the American Medical Association to the Library of the Academy of Medicine of Toledo and Lucas County.——Dr.

Dorsey W. Fellers, Bloomville, has been reelected a member of the Seneca County Board of Health for five years.

PENNSYLVANIA

Damage Suits Following Epidemic.—Nine residents of New Milford have brought damage actions, aggregating $170,000, against the New Milford Water Company, following the recent outbreak of typhoid in that village. According to the New York *Times*, there were eighty cases of typhoid fever and several deaths, and health officials declared that the source of the epidemic was in the water supply (The Journal, March 27, p. 961).

Distribution of Income from Frick Estate.—Judge Mitchell of Orphans Court, Pittsburgh, ordered the distribution of more than $1,000,000 to beneficiaries of the residuary estate of the late H. C. Frick, the sum representing income from the estate. Among the beneficiaries were various Pittsburgh hospitals and charitable and educational institutions; Princeton University receives $300,000; Massachusetts Institute of Technology, $100,000 and the Society of the Lying-In Hospital, $30,000.

County Public Health Associations.—The work of organizing county health associations in Pennsylvania is progressing satisfactorily; according to the state secretary of health, the plans now involve the organization of all the counties in the state before Dec. 31, 1926; Beaver, Bradford, Centre, Clearfield, Delaware, Erie, Lackawanna, Lawrence, Luzerne, Mercer, Northampton, Schuylkill and Tioga will be organized in the near future. The Allegheny Public Health Association recently held its second annual meeting in Pittsburgh, and the Bedford County Public Health Association recently held its second meeting. The county units are members of the state public health association, and are the means of standardizing and disseminating preventive and constructive health work throughout the state.

Society News.—Dr. Walter E. Dandy, Johns Hopkins Hospital, Baltimore, delivered the R. W. Stewart Memorial Lecture before the Pittsburgh Academy of Medicine, May 6, on "The Diagnosis and Localization of Brain Tumors."——The Women's Auxiliary of the Philadelphia County Medical Society presented a Steinway piano at the dedication of the society's new home in April; the directors of the medical society have assigned one room in the building for the use of the auxiliary.——Dr. Francis Carter Wood, New York, gave a postgraduate lecture before the Allegheny County Medical Society, Pittsburgh, May 27, on "The Blair Bell Lead Treatment for Cancer."——The Pittsburgh Ophthalmological Society gave a dinner, May 28, at the University Club in honor of Prof. Leonhard Koeppe of the University of Halle, Germany, who addressed the society on "Early and Differential Diagnosis of Several Forms of Cataract with the Slit Lamp."

Philadelphia

Personal.—Alba B. Johnson, former president of the Philadelphia Chamber of Commerce and for many years closely identified with Jefferson Medical College, has been elected president of that institution to succeed the late William Potter.

Prizes to Undergraduates.—The dean of the University Pennsylvania Medical School announced, May 2, that Eugene M. Landis, Philadelphia, for the third consecutive year had won the first prize for the best piece of research to be done by a medical student of the university; L. A. Rademaker, Tacoma, Wash., received second prize, and S. David Glusker, Brooklyn, received the third prize.

Society News.—Dr. Wilmer Krusen, director of health, was the guest of honor at the eightieth annual anniversary banquet of the Northern Medical Association, Philadelphia, Majestic Hotel, May 17.——Dr. Harold H. Marvin, Yale University Medical School, New Haven, Conn., addressed the Rush Society at the College of Physicians, May 18, on "Use and Choice of Diuretics in Cardiac Patients."——The Medical Club of Philadelphia held a reception at the Bellevue-Stratford Hotel, May 27, in honor of the surviving original members, of whom there are fourteen.——Dr. Frederick S. Baldi has been nominated as 1927 president of the Philadelphia County Medical Society, and Dr. Isidor P. Strittmatter, president-elect; Dr. Orlando H. Petty, vice president, and Drs. Henry G. Munson and Edward A. Shumway, secretary and treasurer, respectively, to succeed themselves; at this meeting the society voted to change the by-laws so as to permit the nomination and election of a president-elect, so that he may become familiar with the business of the society before induction into office.

TENNESSEE

State Medical Election.—At the annual meeting of the Tennessee State Medical Association, Memphis, May 11-13, Dr. Ernest R. Zemp, Knoxville, was elected president; Drs. Thomas B. Yancey, Kingsport, William F. Cannon, Fayetteville, and James L. Dunavant, Henning, vice presidents; Dr. John O. Manier, Nashville, treasurer, and Dr. Joseph F. H. Gallagher, Nashville, secretary-editor.

New Medical Organizations.—After many years of inactivity, the Warren County Medical Society has reorganized; Dr. Elbert L. Mooneyham, Rock Island, was elected president, and Dr. John S. Harris, McMinnville, secretary.——After five years of inactivity the Morgan County Medical Society has been reorganized; Dr. William E. Gallion, Oakdale, is secretary-treasurer.——The Giles County Medical Society has also been reorganized with Dr. James P. K. Blackburn, president; Dr. James A. LaRue, secretary, and Dr. George D. Butler, treasurer, all of Pulaski.

TEXAS

Society News.—Major Shelley U. Marietta, Medical Corps, U. S. Army, addressed the Bexar County Medical Society, recently, on "Indications for Surgical Procedure in Pulmonary Tuberculosis," and the discussion was opened by Lieut. Col. Raymond F. Metcalf, U. S. Army, stationed at Fort Sam Houston.

Hospital News.—An anonymous donor has given $75,000 to be applied on building a modern hospital for the negroes of Houston, the site for which has already been purchased. The gift will be supplemented by a gift from the city.——The contract has been let for the construction of the Fred Roberts Memorial Hospital at Corpus Christi, to cost about $60,000.

"Divine Healer" Convicted.—Mrs. Clyde Bell, Fort Worth, was found guilty of practicing medicine without a license by a jury, April 23, and sentenced to one hour in jail and a $100 fine, it is reported. The *Texas State Journal of Medicine* says that a patient testified that Mrs. Bell promised to cure a cancer of the breast by laying her fingers on the tumor; the patient was given some pills also and was charged $140.

WISCONSIN

Society News.—Dr. Clifford G. Grulee, Chicago, addressed the Milwaukee Pediatric Society at the Milwaukee Children's Hospital, April 14, on "The Intraperitoneal Transfusion of Citrated Blood in Anemia Pseudoleukemia, von Jaksch-Hayem Disease."

Personal.—Dr. John J. Bowes, assistant superintendent of the Central State Hospital for the Insane at Waupun, has resigned.——Dr. Charles Reineck has been elected chairman of the board of health of Appleton.——Arthur S. Pearse, Ph.D., professor of zoology, University of Wisconsin, has resigned to accept a professorship in Duke University, Durham, S. C.; Dr. Pearse is now on leave studying in the London School of Tropical Medicine.

Dr. Brown Resigns.—The State Board of Control of Wisconsin has accepted the resignation of Dr. John F. Brown as superintendent of the Central State Hospital for Insane, Waupun, who has been in poor health for some time. Dr. Brown, according to the *Wisconsin Medical Journal*, has been superintendent of this hospital since 1919, and has been associated with state institutions for twenty-three years, serving as superintendent of the school for the blind at Janesville, superintendent and physician at the School for Dependent Children at Sparta, and as physician at the state prison for seven years.

GENERAL

Pacific Northwest Medical Association.—This association will meet at Spokane, Wash., July 1-3, at the Davenport Hotel. Among the speakers will be J. B. Collip, Ph.D., and Drs. George W. Holmes, Boston; E. H. Mason, Montreal, Canada; Harry L. Parker, Rochester, Minn.; George Dock, Pasadena, Calif.; Arthur Steindler, Iowa City, and John Whitridge Williams, Baltimore.

Health Survey of Mexico.—Frederick L. Hoffman, LL.D., consulting statistician, Prudential Insurance Company of America, will leave New York, June 10, to make a comprehensive survey of health conditions and methods being used in Mexico to eradicate disease. Dr. Hoffman will be accompanied by two assistants, and after a study of the native Indian population in Arizona and New Mexico will begin the Mexican survey at Nogales, and then go to Guadalajara, Mexico City, Vera Cruz, Yucatan, Oaxaca, the Isthmus of Tehuantepec, and possibly into Central America

Questionnaires Deplored.—At the twenty-third annual meeting of Experimental Psychologists, held at the University of Pennsylvania, Philadelphia, April 5-7, a resolution was adopted as follows

> *Resolved*, That this meeting deplores the increasing practice of collecting administrative or supposedly scientific data by way of questionnaires, and
>
> That the meeting deplores especially the practice under which graduat students undertake research by sending questionnaires to professional psychologists

American Journal of Surgery Changes Publishers.—With the May issue, the *American Journal of Surgery* passes into the hands of Paul B Hoeber, Inc, New York The editor continues to be Dr Walter M Brickner, with whom will be associated a new editorial board The publisher announces in the current issue a gradual elimination of advertising, except that which meets the standards of the Council on Pharmacy and Chemistry and the Council on Physical Therapy of the American Medical Association The publisher also announces an increase in the size and improvement in typography Special attention will be given to general industrial and traumatic surgery, anesthesia and physical therapy

Directory of Otolaryngologists—The American Board of Otolaryngology has just issued a directory of those physicians who have successfully passed the examination and received their certificates which signify that the holders are, in the minds of the board, duly qualified to practice in the field of otolaryngology In the directory of the American Medical Association, there are more than 6,000 physicians who are endeavoring to specialize in the field of otolaryngology Most of these are general practitioners who have had no special preparation and could not receive the certificate from the American Board of Otolaryngology The directory which has just been issued by the board will assist physicians as well as patients, in finding out what men in the various centers have had the preparation that qualifies them to practice in this field

Smallpox in 1925.—Reports received from state health officers by the American Association for Medical Progress indicate that more smallpox was reported in the United States during 1925 than in any other country except India The total number of cases reported was 43,193, which is an improvement over the preceding year, when the total number was 56,351. While most of the states did not report whether the patients had been vaccinated or not, this fact was reported for most of the cases from seventeen states and the District of Columbia, and among 10 636 cases so reported, 9,660 of the patients had never been vaccinated, and 751 had been vaccinated from seven to fifty years previously Thirteen states each reported more than 1,000 cases of smallpox in 1925, California leading the list with 4,921, Alabama was second with 4,288, and Ohio third with 4,018 The six New England states altogether had only 102 cases, ninety-four of which were in Rhode Island

Society News.—At the annual meeting of the American Radium Society, Dallas, Texas, April 19 20, Dr Albert Soiland Los Angeles, was elected president, Dr Curtis F Burnam Baltimore, president-elect, Drs Burton J Lee, New York, and Edward H Skinner, Kansas City, Mo, vice presidents, Dr Edwin C Ernst, St Louis, secretary, and Dr Sanford M Withers, Denver, treasurer ——The American College of Physicians will hold its eleventh annual clinical congress at Cleveland the week of Feb 20, 1927 Further details may be obtained by writing Mr E R Loveland, executive secretary, c/o The Covington, Thirty-Seventh and Chestnut streets, Philadelphia, Dr John Phillips, Cleveland, has been elected general chairman of the congress ——At the annual meeting of the American Association of Genito-Urinary Surgeons, May 12, Dr James A Gardner, Buffalo, was elected president, and Dr William C Quinby, Peter Bent Brigham Hospital, Boston, secretary The next annual session will be at Atlantic City

Bovine Tuberculosis Decreasing—The percentage of tuberculous cattle in the United States decreased from 4 per cent in 1922 to 2 8 per cent in 1926, according to a survey completed, May 1, by the U S Department of Agriculture This has been brought about by cooperation between federal state and county forces, and indicates that by 1936 about 31 per cent of the country will have reduced the percentage of bovine tuberculosis to less than 0 5 per cent The proportion of diseased cattle now varies from more than 23 per cent in some counties to less than 0 5 per cent in others. Most of the infection is confined to a comparatively small area, about 73 per cent of the reactors yet to be condemned being in 411 counties, the other 27 per cent of diseased cattle are scattered throughout the remaining 2,658 counties, where the average infection is less than 3 per cent The department of agriculture states that it is comparatively easy, when funds are available, to free any county of bovine tuberculosis which has less than 3 per cent infection, and that the problem is one of proper initial testing and sufficient quarantine measures to protect against reinfection

FOREIGN

Tax Stays on Nobel Fund.—The Swedish Parliament has rejected a proposal to remove the tax from the Nobel Prize Fund, which, according to *Science*, was made by members of all political parties Sweden has had, from the beginning of the fund, an income from this tax of 10,000,000 crowns, last year, it is said, the tax was higher than the prize sum given in that year

Berlin Charlatan Goes to Prison.—The Potsdam court has sentenced to four years' imprisonment a drugless practitioner, a former mechanic, on account of the death of a girl in diabetic coma after he had been treating her for eighteen days She had been treated in a sanatorium and had been instructed to keep up the insulin treatment, but the charlatan told her to eat sugar, honey and other sweets instead, which induced fatal coma on the sixteenth day. The state prosecutor had asked for a penalty of two and a half years' imprisonment but the court imposed four years The case is described in the *Deutsche medizinische Wochenschrift* 52:370, 1926

Strike at Canton Hospital—The South China Branch of the China Medical Association unanimously adopted a resolution April 8, protesting against the inhuman action of the Miscellaneous Workers Union, which ordered all workers of the Canton Hospital Canton, China, to leave their work and the hospital premises and caused the hospital gates to be picketed preventing Chinese patients and others from entering the hospital preventing food being taken into the hospital for Chinese patients and staff, and cutting the water and telephone services When this resolution was passed, the pickets were still at all the gates of the hospital armed with clubs The Canton Hospital the resolution says, introduced modern medicine into China, and for ninety years has served the community as a charitable medical institution

Personal.—Prof M Couto president of the Brazilian Academy of Medicine was tendered a reception by the French Academie de medecine at Paris He presented the president, Professor Bar, with the diploma appointing him an honorary member of the Brazilian organization, with the symbolic collar and address of tribute from the Rio Academy He also delivered an address on "The Syndrome of Perforation of the Aorta"——The radiologist of the Bretonneau Hospital, Paris M Lobligeois, has had an arm amputated, the fourth operation since 1925 for professional injury. Dr G Piana radiologist of the Genoa public hospital, is another victim of radiologic professional injury, requiring amputation of the left arm ——The conference on physical training and school hygiene of the Northland is to meet at Copenhagen in August Dr H P T Ørum is in charge of the arrangements ——Dr E Roesle, Berlin, has been appointed a member of the international committee for standardizing vital statistics The next revision of the nomenclature is to be made in 1927, and the work is already under way ——Dr Albert Grotjahn, Berlin professor of social hygiene, has been appointed corresponding member of the League of Nations' committee for educating the public in hygiene ——Prof L Morquio, Montevideo, delivered an address at Paris on "Hydatid Cysts in the Lungs in Children" He was the delegate from Uruguay to the recent International Child Welfare Congress at Geneva.

Deaths in Other Countries

Dr John William Smith, emeritus professor of surgery, Victoria University of Manchester, England, April 13, aged 61 ——**Dr T. Wyder**, professor of gynecology, Zurich, author of an "Atlas for Gynecologic Examination" and other works, aged 72 ——**Dr K. Reifferscheid**, professor of gynecology, Gottingen, aged 53 ——**Dr Jules Glover**, Paris, the laryngologist of the Conservatoire de musique, whose application of electric auscultation to different parts of the body has proved useful in aviation ——**Dr F. Lentz**, Tournai, formerly president of the Belgian Académie de medecine, aged 86 ——**Dr M Henseval**, professor of bacteriology at Ghent, aged 52 ——**Dr Carl Ruge**, Berlin, aged 79, author of a "Manual of Gynecologic Diagnosis"——**Dr Bartolome Podesta**, Buenos Aires, was shot and killed, May 11, by an unknown assailant

Foreign Letters

LONDON

(From Our Regular Correspondent)

May 8, 1926.

Death of Dr. Axham

Dr. Axham has died at the age of 86. He had been in failing health for some time. His name was removed from the Medical Register in 1911 because he acted as anesthetist to Mr. Barker the bone-setter, and because he refused to discontinue this service. When the honor of knighthood was conferred on Mr. Barker, it was widely felt by the public that Dr. Axham should not longer remain under the ban of his profession, many of the most prominent members of which had publicly expressed their admiration of Sir Herbert Barker's work. An effort therefore was begun to induce the general medical council to reconsider its decision. This attracted the widest public attention and assumed, in a short time, the dimensions of an agitation. The general medical council, however, declared that it was powerless in the matter. Dr. Axham's professional qualifications, which entitled him to registration, had been removed. In this impasse, his supporters turned to the Royal College of Surgeons, but this body refused to listen to them. The Royal College of Physicians of Edinburgh, however, of which body Dr. Axham had been a licentiate, gave him back his license. Then a further appeal to the general medical council was made, and it was urged that a special meeting should be called to consider the Axham case. This request was refused. The case was set down for hearing in the coming summer session of the council. As might be expected from the previous reports in The Journal on the case, Dr. Axham's death has aroused general sympathy in the lay press and criticism of the general medical council, which on the whole is moderate. The *Times* says: "The Axham case is now closed, and the opportunity which the general medical council had of performing a singularly attractive act of grace has gone. But the public issues raised by this case still remain. At the time when his name was removed from the medical register, Dr. Axham addressed to us a letter in which he set forth clearly and in dignified language the reasons which had impelled him to give assistance to Mr. Barker. Dr. Axham, then nearing 65 years of age, was at great pains to satisfy himself, before he took the most momentous step of his life, that this step was in fact his duty. He paid forty-five visits to Mr. Barker's consulting room. He saw 'several kinds of joint injuries, deformities and displacements treated entirely by manipulation, such as is not practiced at any hospital in the metropolis.' His decision exercised an important effect in bringing to the notice of the medical profession the value of manipulative surgery. Other journals are less restrained and describe Dr. Axham as a 'medical martyr' and refer to a 'vendetta against an aged doctor even when he stood on the threshold of eternity.' A demand is made by several journals for the reconstitution of the general medical council. In its obituary notice the *Lancet* states that 'the medical profession had much sympathy with Dr. Axham in the late phases of the contentions around him, though quite aware that the criticisms directed against the general medical council were frequently erroneous.'"

Health of the Army

The importance of health among soldiers, whether on active service or under peace conditions, is emphasized by the publication of the Army Manual of Sanitation (1926), designed especially for regimental officers and other ranks. It is pointed out that a large proportion of the diseases of armies is preventable, and as a rule many more men are lost through disease than through enemy action. Though losses from disease are more acutely felt during a campaign than in time of peace, yet the waste of men's services in peace time through preventable disease is a serious matter to the army. A chapter of the manual is devoted to environment in relation to health, in which many points peculiar to the soldier are dealt with. For instance, it is stated that a man can carry a marching load equal to one third of his own weight without undue exertion, but any marked excess over this amount means that fatigue will set in rapidly and the increased work requires a greatly increased supply of food; and, again, a soldier in marching order may lose by perspiration alone nearly a quart of water during a march of 8 miles, even in a temperate climate. The chapter which deals with sanitary organization on active service states that the sanitary organization of an army in the field is based on three principles: First, the commander of every unit and formation is responsible for the sanitary condition of the quarters or localities occupied by his command; second, every commander has available a representative of the medical services responsible for giving advice and technical recommendations; and, finally, special sanitary personnel is provided in all units, formations and areas to supervise and carry out sanitary measures beyond the skill or training of the troops.

Drug Addiction

The prevention and arrest of drug addiction was dealt with by Sir William Willcox, in a presidential address before the Society for the Study of Inebriety. He said that drug addiction was not very prevalent in this country, but parts of the British empire were places where addiction drugs were being grown and produced, and in parts of the empire drug addiction was very prevalent. In America, drug addiction was a serious problem indeed, and it had been estimated that in the United States there were more than a million drug addicts, and in the city of New York 1.8 per cent of the population were addicts. Drug addiction is a disease rather than a vice, said Sir William, and, like other diseases, it is infectious. It is spread by psychotherapeutic methods, one person influencing another. Drug addiction is a real menace to the world, and it is necessary that Britain should play its part in the fight against it. We were immeasurably more successful in this country in controlling traffic in addiction drugs than were the Americans, and an enormous amount of drugs got to the public in America by illegal ways. It was important that members of the medical profession should realize that it was only in exceptional cases that morphine and such drugs should be prescribed, especially hypodermically. Other drugs should, if possible, be administered, and these dangerous drugs should never be employed for the relief of mental strain, worry, grief or distress.

Mild Outbreak of Influenza

A considerable, though mild, outbreak of influenza is in progress in most parts of the country. The type of the disease seems to be "gastric," and the symptoms complained of, in most cases, are headache, dyspepsia and lassitude. The condition tends to recur at short intervals, so that some of the victims are ill over several weeks. This is the thirty-fourth week, calculating from the week beginning Nov. 12, 1921, that a sharp epidemic began. Season after season confirmation has been furnished of the observation of Dr. Brownlee that influenza shows a definite periodicity. So far, no explanation of this periodicity has been furnished.

Poison Dangers

Dr. Edwin Smith, lecturer on forensic medicine and toxicology at St. Thomas' Hospital, and coroner for northeast London, addressed a meeting of nurses and others at the hospital and nursing conference on poisons. He said that had he been addressing a meeting of physicians he should have taken the opportunity of reminding them that, just as a hospital should have its poison cupboard, so the physician should have a properly equipped bag for use in case of poisoning. There was much laxity in the matter. Very few physicians, he declared, were prepared for adequate attendance on cases of poisoning. They simply relied on finding what they wanted when they got to the patient and, while usually prompt in administering an emetic, they also showed a surprising want of care or knowledge in following up the treatment with the proper antidote. That was a somewhat serious criticism, but it was based on accurate knowledge of the conditions of medical practice both in London and elsewhere. Nurses, he said, had been led into error, through mistaking the symbols used in physicians' prescriptions, and in a badly written prescription the symbol for a drachm might easily be mistaken for that of an ounce. The present poison regulations were drastic in one sense but very unsatisfactory in another. No one could get from a pharmacist a hundredth of a grain of arsenic except by a procedure hedged round with safeguards against accident and crime. But such poisons as spirits of salt and salts of lemon could be sold at an oilshop, even to a child, without hindrance. Further, the bottle or package in such cases was required to be labeled "Poisonous," a word which surely tended to mislead by suggesting something of lesser virulence hardly calling for the more definite name of "Poison."

The Uses of Radium

The effects of the uses of radium on malignant and nonmalignant diseases in nine research centers during 1924 is summarized in a pamphlet just issued by the medical research council. Five of these centers are in hospitals in London, and the other four are in hospitals at Birmingham, Cardiff, Aberdeen and Dublin. The experiments have been carried out with a stock of radium salt which had been collected for military purposes during the war. Further quantities of radium salt had been provided by the British Empire Cancer Campaign, while the same organization is defraying the expenses of supplying radon from the center at the Middlesex Hospital.

With regard to cancer in the breast, it is stated that radium has a definite therapeutic value; local recurrences, treated by the method of surgical insertion, are often held in check, and may sometimes disappear after the use of comparatively large doses of radium. For cancer of the uterus, a palliative radium treatment has proved of great value. Hemorrhage ceases in nearly all of the cases, the local growth disappears in a large percentage, the patients feel better and put on weight, and in many instances life is prolonged. The histologic evidence proves that where the growth is localized, the malignant cells have in certain cases been completely destroyed. The value of radium therapy in malignant growths of the mouth, nasopharynx, larynx and esophagus is stated to be intimately bound up with the technic adopted. The irradiation of tumors in these sites by numerous, though weak, radium sources, applied for a long time, is a hopeful development, but results on a larger number of cases are needed before any definite conclusions on this technic can be reached. Another conclusion drawn is that radium therapy is effective in a large porportion of rodent ulcers. There is, however, a tendency for recurrence. In cases in which there has been a recurrence of activity of the cells at the surface of the growth, this points to unusual resistance of such cells to irradiation.

Roentgen-Ray Martyr Honored

Major J. Hall-Edwards, the Birmingham radiologist, has been elected honorary life member of the British Medical Association. Dr. Hall-Edwards has had his left hand and forearm and the four fingers of his right hand amputated as the result of dermatitis. Recently he has suffered from recurrent heart attacks, but he continues to take an active interest in public life as a member of the Birmingham city council.

The Journal of Neurology and Psychopathology

The British Medical Association has decided to publish the *Journal of Neurology and Psychopathology*, which has existed since 1920 and was started to take the place of the former *Review of Neurology and Psychiatry*, a valuable periodical that ran from 1903 to 1918. The aim of this journal has been to supply abstracts and reviews covering the whole field of neurology and psychopathology, for which the need is felt by workers in those subjects. The editor is Dr. S. A. Kinnier Wilson. The *Journal* is a quarterly and the annual subscription is $7.50, for which orders should be sent to the financial secretary, British Medical Association, Tavistock Square, London, W. C. 1.

Hydrocyanic Acid in Shoe Cleaning Preparations

By a circular of March 23, 1926, the federal department of public health states that recently preparations containing hydrocyanic acid have been on sale for cleaning silver and brocade slippers. The sale of these dangerous products is prohibited by article 38 of the Swiss federal law relating to foodstuffs and various ordinary preparations for household use, and the public is therefore warned against their use.

Tuberculosis Control in Denmark

J. Ostenfeld and G. E. Permin have presented a detailed report on the control of tuberculosis in Denmark to the Swiss federal department of public health. The state pays from three fourths to five sixths of the cost of treatment. The question of payment never excludes tuberculosis cases from any of the establishments mentioned by law. The public charities maintain the family during the treatment of its wage earner. Patients are clad and transported at the expense of the municipality. The expenses of state recognized antituberculosis dispensaries are met, one third by the state, one third by the municipality and one third by private initiative. Besides economic measures, the law covers a number of prophylactic and sanitary measures, such as reporting of cases of pulmonary or laryngeal tuberculosis and reporting of all deaths from tuberculosis. Furthermore, disinfection, isolation or hospital treatment may be ordered when necessary. In order to protect children, a wetnurse cannot be accepted unless she has a medical certificate specifying that she is free from tuberculosis; subjects with infective tuberculosis cannot be employed in any institution where children are cared for. Private persons cannot take children to board unless provided with a medical certificate showing that persons in the family are not affected with contagious tuberculosis. Children with infective tuberculosis are barred from public schools. The department of public instruction provides instruction for diseased children. Every teacher must be free from infective pulmonary or laryngeal tuberculosis. If a public employee contracts infective tuberculosis after being appointed, his case is investigated, and if he is discharged he receives an annuity equivalent to two thirds of his salary. The law excludes subjects with tuberculosis from bake-shops and confectioners. Throughout Denmark there are stations for diagnosis where examination of the sputum is gratuitous.

Epitaph Prejudicial to Medical Profession

The civil court of Montpellier recently handed down a decision as follows: An epitaph injurious to physicians or the medical profession cannot be tolerated. The test case was that of a man who lost his wife and accused Dr. P. Delmas, professor of obstetrics at Montpellier, of having caused her death. The husband had inscribed on a black stone in gold letters "Victim of the Professors," and this was placed over the vault in a little chapel. Learning this, Professor Delmas and the medical syndicate of Hérault conjointly sued the husband. The court ordered the husband to remove the words "Victim of Professors" within one month, and if he did not comply within this time to pay twenty francs ($0.65) daily until the removal of the words. The court also ordered the husband to pay one franc to Delmas and 500 francs ($16) to the syndicate, as well as costs of the trial.

Trial of a Quack

In La Chaux-de Fonds (Switzerland) a Russian woman pretended that she possessed special power at the finger tips, similar to radium, and could cure certain diseases. Some witnesses stated that they had been improved after the healer had placed her finger tips on them. The healer did not exact a fee, but accepted presents. She prescribed no remedy, her mere personal fluid being enough to work a cure. She was found guilty of the illegal practice of medicine.

Case of Lipodystrophy

A case of progressive lipodystrophy in a boy, aged 10 years, has been in the university clinic of Geneva. As pointed out by Professor Roch, this case is interesting in several ways. In the first place the onset was only one year ago. The affection evolved very rapidly because when the patient was first seen the picture was nearly complete. On the other hand the picture was not perfect. Although the fat atrophy of the upper half of the body was practically complete, the fat hypertrophy of the lower part of the body was incomplete, the amount of fat being hardly greater than normal. The patient presented a distinct polymicro-adynia. There is no clear pathogenesis but it is possible that the involvement of the lymphatics had played a part in the development of the progressive lipodystrophy. The patient had quiescent tuberculosis, which had attacked the lymphatics and probably also the endocrine glands, whose part in disturbances of growth and metabolism is now recognized. Of late, it has been shown that the lymph nodes and lymphocytes throw a lipolytic ferment into the circulation—a lipase—the function of which in fat transformations is not fully elucidated. For this reason Professor Roch stressed the coincidence of a disturbance in the distribution of the subcutaneous fat and the general involvement of the lymphatic system.

RIO DE JANEIRO

April 15, 1926.

Treatment of Lupus

Dr. Alvaro Alvim states that the alleged new cure for lupus reported by Dr. Auregan to the French Dermatological Society is far from new. This treatment consists of a deep scraping followed by applications of potassium permanganate. While the method cures, says Alvim, he does not use it as it is too painful and antiplastic. Alvim reports that he has cured all his patients, using first ultraviolet rays or Finsen light, followed by embrocations with a freshly prepared potassium permanganate solution. Sometimes the tubercles on the surface are burned with the actual cautery. Radiotherapy destroys all traces of the disease.

Spider Venom

In the second volume of *Memorias do Instituto Butantan*, Drs. Vital Brazil and J. Vellard have a long article on the poison of spiders. They studied five different species: *Ctenus ferus*, Perty; *Ctenus nigriventer*, Keys; *Trechona venosa*, Latr.; *Nephila cruentata*, Fabr., and *Lycosa raptoria*, Walck. With direct bites, the results are variable, according to the condition of the spider, the temperature and other factors. To obviate this uncertainty, several solutions of the poison were prepared. These yielded results somewhat less active than those secured with bites. With a dry poison treated with saline solution, the results came closest to those of natural poison. The venoms of *Ctenus ferus* and *Ctenus nigriventer* are very active and affect exclusively the nervous system. On the contrary, that of *Nephila cruentata* is rather weak, and its action is purely local. The venom of *Lycosa raptoria* acts also only locally but is very potent. This spider is incriminated in the necrosing arachnidism cases reported at São Paulo.

Certain neurotoxic spider poisons possess an activity comparable to that of the strongest snake venoms; on the other hand, others cause only a more or less extensive local necrosis. Practically all those studied (more than twenty species) failed to exhibit any lytic action on blood cells, as well as any proteolytic or coagulating effect.

In any case of bites by poisonous spiders, specific serum therapy should be used. It is possible to prepare a very active serum against spider venom. The serum of a sheep that had received for two weeks daily injections of *Ctenus ferus* neutralized an appreciable quantity of this poison. A very active serum against the poison of *Lycosa raptoria* was obtained by a similar method. These serums are strictly specific and do not protect against other species. Likewise, snake or scorpion antiserums are useless against spider venom. It proved difficult to study the neutralizing action of the blood serum of spiders on their own serum. A 0.1 cc. dose of serum proved ineffectual; a 0.5 cc. dose was strongly toxic. The symptoms caused by the blood serum of several species of spiders were identical, but each poison acted differently.

Spider poisons are stable at low temperatures. They begin disintegrating at 65 C., but total destruction takes place only at 100 C. They are also resistant to the various chemical agents used for attenuation. The most active substances are potassium permanganate (1 per cent solution) and tenth normal solution of sodium and ammonia (25 per cent). Sodium thiosulphate (50 per cent), chromic acid and ammonia (1 per cent) proved rather ineffective.

Artificial Pneumothorax

Dr. Ary Miranda has discussed the immediate results of pneumothorax in tuberculosis of the lung. This method was used in 117 cases treated at the tuberculosis division of the public health department. In twenty cases, the process proved impracticable, because of pleural involvement; in twelve it had to be abandoned, as the collapse proved inadequate; in seventeen, lesions appeared in the opposite lung; eighteen patients refused to continue the treatment, and one died after the pneumothorax failed to stop the downward course. In the remaining forty-nine, the method modified favorably the symptoms, and even permitted the patients to return to their former occupation. It is interesting to observe that the air hunger so prevalent among tuberculous patients is a reflex phenomenon and not the direct result of the decreased breathing surface.

Late Localized Tetanus

Dr. Americano do Brazil has reported a case of late local tetanus with pleurothotonus treated in the Army Central Hospital. The patient, after a bullet wound in the left hip, received the usual antitetanic injection. Two months and ten days afterward, he developed tetanus symptoms localized in the wounded part. The patient finally recovered after receiving 657 cc. of serum. Trismus, nuchal rigidity and abdominal muscle reactions were transitory, the predominant symptom consisting in contractions in the left lower extremity. According to Lumière and Courtois-Suffit, there has not been so far a single case of local tetanus with traces of pleurothotonus.

Cholecystography

Dr. Manuel de Abreu presented to the Society of Medicine and Surgery the first report prepared here on cholecystography. His records showed graphically that after an injection of tetrabromphenolphthalein in normal subjects, the gallbladder casts as clear a shadow as the stomach after an injection of bismuth. Dr. de Abreu also showed the roentgenograms as well as the surgical specimen in a case of calculus impacted in the cystic duct. Graham-Cole's test had been negative; i. e., the gallbladder was invisible.

ITALY

(From Our Regular Correspondent)

April 15, 1926.

A Series of Lectures on Neoplasms

Under the auspices of the Istituto sieroterapico of Milan, a series of lectures on neoplasms will be held in that city, from April 12 to May 14. At the same time, Professor Rondoni will deliver a course of lectures on endocrine pathology. There will also be a theoretical and practical course in immunology and serodiagnosis, occupying two weeks in May.

Italian Colonial Medicine

In an open letter, directed to the prime minister, Professor Sangiorgi of the University of Parma emphasizes the need of a genuine Italian colonial medicine, which today does not exist. No one has been assigned the official task of studying the medical geography of the various regions that make up our African possessions, nor the numerous types of diseases, of both man and animals, peculiar to the particular climates. Professor Sangiorgi proposes, therefore, that Italy should establish in its colonies special biologic institutes, provided with personnel and equipment, for the study of problems of colonial medicine, preferably of the type of the Pasteur institutes such as France has created in its colonies. As points of departure for the organization of such institutes might possibly be taken the present vaccination institutes existing in Eritrea (at Asmara) and in Italian Somaliland (at Merka). Others should be established at Tripoli, Derna and Rhodes (for the islands of the Aegean Sea).

Congress of the Italian Society of Neurology

The Società italiana di neurologia held its annual meeting at Turin, April 7-9, under the chairmanship of Senator Leonardo Bianchi. The congress comprised six sessions, during which numerous communications on the physiopathology of the nervous system were presented. It is the custom of the Society of Neurology not to have presented at its congresses official papers on subjects selected in advance. During the congress, special honors were shown to Prof. Eugenio Tanzi, occupant of the chair of mental and nervous diseases of the University of Florence, on the occasion of his becoming a septuagenarian. The day following, Professor Morpurgo presented to the conventionists Prof. Camillo Golgi, who had been counselor of the Società di neurologia since its foundation. Catania was chosen as the meeting place for the next congress.

League for the Promotion of Dental Hygiene

Founded in Turin, last October, with the object of promoting the care and prevention of dental caries, particularly in children, the Lega italiana per la propaganda d'igiena odontoiatrica scolastica has grown rapidly. In the schools, it has introduced a dental record card for the use of physicians entrusted with the medical examinations and to aid in the compilation of eugenic records. The league has induced dealers in school supplies to print maxims of dental hygiene on tablets and composition books, and has had made and distributed a type of toothbrush specially adapted for children. The league has appointed certain Italian stomatologists as its representatives in various provinces. It plans also to commission Drs. Rivano and Marangoni to deliver at Turin a series of lectures on the anatomy, physiology and pathology of the dental apparatus, with especial reference to children.

The Death of Giuseppe Gradenigo

The death of Prof. Giuseppe Gradenigo, director of the otorhinolaryngologic clinic at the University of Naples, has been announced. Professor Gradenigo was born in Venice in 1859. He carried out important researches on the embryology of the ear. He is the author of approximately 400 articles, treatises and books. His researches on familial deafness, experimental phonetics, telephonic acoumetry and otic acoumetry are likewise valuable. In 1889, he founded, in collaboration with Professor De Rossi of Rome, the monthly review *Archivio italiano di otologia, rinologia e laringologia.* During the war, he held the rank of lieutenant colonel, devoting much of his time to the study of methods of selecting air pilots. He was the recipient of many honors at home and abroad.

BERLIN

(From Our Regular Correspondent)

April 17, 1926.

The Congress of Internal Medicine

The annual session of the Deutsche Gesellschaft für innere Medizin was held in Wiesbaden, April 12-15, under the chairmanship of Professor Pässler of Dresden. The three main topics presented during the first three days of the session dealt with (1) the therapy of neurosyphilis; (2) the blood as a reflector of somatic processes, and (3) the pathology and therapy of asthma. The remaining papers or addresses (around 110) either treated subtopics of the main themes or were concerned with diseases of the nervous system, of the heart and kidneys, or of metabolism.

TREATMENT OF NEUROSYPHILIS

The papers on therapy of neurosyphilis were presented by Professor Spielmeyer of Munich and Professor Wagner-Jauregg of Vienna. Spielmeyer discussed, more particularly, theoretical researches on treatment of neurosyphilis. In neurosyphilis, tabes and general paralysis occupy a distinct position. They are not mere syndromes within the limits of neurosyphilis. The possibility of arrest of tabes can be demonstrated anatomically. In general paralysis, the clinical term "stationary" is not usually justified anatomically, since the process continues to develop, although possibly imperceptibly. There have been perhaps a few cases in which a cure with defect could be demonstrated. The histologic picture in the cases of general paralysis in which malaria inoculation has proved successful resembles the findings in the cases of paralysis that have become spontaneously stationary. The principle involved in this method has not been cleared up as yet by the anatomic findings. A special causative agent might, according to laboratory experiments, constitute an obstacle to specific therapy (Ehrlich's trypanosome studies, etc.). Various strains of spirochetes occur. There is also evidence of an early but not of a late neurotropy. The theory that antisyphilitic treatment tends to produce neurosyphilis needs to be more definitely established before conclusions can be drawn. The assumption that, in therapeutics, the spinal fluid-blood barrier constitutes the chief obstacle appears doubtful. Other factors may come into play; for instance, peculiarities of the organism, or the breakdown of defense forces. Wassermann's proposals that the process be imitated that presumably takes place in the therapy of secondary syphilis have not proved successful. Laboratory experiments have given no insight into the question of the breakdown of the defense forces of the organism. They have not revealed failure of important blood functions, nor loss of capacity for phagocytosis. Attempts to prove weakness of the defense forces from the histologic picture also have failed.

Professor Wagner-Jauregg discussed the modern treatment of neurosyphilis. All treatments act for the most part by stimulating the defense forces of the organism against syphilis. The tuberculin-mercury procedure was instituted in 1900. Numerous remissions of the disease were thereby effected, but in the majority of the cases the improvement was not permanent. The same is true of other treatments, such as the use of vaccines and protein bodies. These experiences led to the treatment of general paralysis by inoculation with malaria (1917). Malaria inoculation should always be combined with other treatment. Recurrences have been noted, but these can doubtless be controlled by more intensive treatment. Retrogression of the disease symptoms and improvement in serologic reactions do not at first run parallel. *But, later on, if the remissions become permanent,* there is gradual improvement in those reactions as well.

The malaria treatment may be used prophylactically in persons who are threatened with general paralysis. African recurrent fever, as introduced by Plaut and Steiner in the treatment of general paralysis, acts in a manner similar to malaria. However, malaria inoculation produces more remissions than recurrent fever. Treatment by malaria inoculation is not dangerous for the environment, provided gamete-free malaria strains are employed. Malaria caused by the bite of the mosquito is not to be recommended, as it is not as susceptible to quinine as is inoculation malaria. The restorative process that follows malaria inoculation or recurrent fever is worthy of intensive study. In tabes as well, especially in the preataxic stages, the treatment by malaria and recurrent fever is effective. In remotely latent cases with persistently positive spinal fluid findings, the treatment as introduced by Kyrle is particularly indicated. Possibly, too, Kyrle's malaria treatment of secondary syphilis has justification.

PRAGUE

(From Our Regular Correspondent)

May 1, 1926.

Institute for Histology and Embryology

The new building of the institute for histology and embryology was opened, April 16, at the Czech Medical Faculty of Prague. In the same building the institute for pharmacology and pharmacognosy will be located. The increasing number of both native and foreign medical students has made it imperative to increase teaching facilities. The construction of the institute was started in June, 1923. The institute for embryology and histology is divided into two parts: one for teaching and one for research. The students' part of the building contains the J. E. Purkinje amphitheater, with 331 seats. Each seat has a small electric lamp which can be used when the amphitheater has been darkened for projections. The Prenant lecture room for eighty students, a seminar room for thirty-four students, an examining room and two laboratories for microscopy, each containing seventy-five seats, complete the teaching part of the institute. The large museum was dedicated to O. Hertwig. The scientific part of the institute is centered about the library. On both sides of the library are laboratories and offices. There are laboratories for photomicrography, drawing, photography, construction of models, microchemistry, neurology and tissue culture. There are also a couveuse, an aquarium and a terrarium. In the basement are a large dissecting room, an operating room for experimental animals, a room for the conservation of preparations, a refrigerating machine and a mechanical workshop. Provision is made for ten workers who are not the members of the staff but who wish to work out clinical problems by laboratory methods. In 1928 the International Congress of Anatomists will be held in the institute.

Anniversary of Ivan Honl

Prof. Dr. Ivan Honl of the Czech Medical Faculty in Prague celebrated his sixtieth birthday, April 23. Having started his work in a single small room in the institute of Professor Hlava, he gradually developed his laboratories into a modern bacteriologic institute. Many papers bear his name. He was the first to demonstrate the effects of *Bacillus pyocyaneus* on suppurative processes. During the war he organized the epidemiologic service in his institute, and not only carried out the diagnostic work but also produced serums and vaccines.

Death of Friedl Pick

Prof. Dr. Friedl Pick of the German Medical Faculty in Prague died in Prague, April 7. He published many papers in the field of internal medicine. Pericarditic pseudocirrhosis of the liver is known as Pick's disease. On account of inherited wealth he was able to give his entire endeavors to the public. Many poor were among his patients. His papers, such as "Jesenius," are of interest to students not only of medical but also of general history.

Clinic for Study of Diseases of Old Age

At the Czech Medical Faculty of Prague, a clinic for study of diseases of old age was opened recently under the direction of Prof. A. Eiselt. The clinic is the outgrowth of a feeling that there is a special pathology of old age as there is of childhood. According to Professor Eiselt's introductory lecture, two groups of diseases of old age must be studied at the clinic: diseases that are specific for old age and ordinary diseases that present a different clinical picture when occurring in old age. The clinic is of special interest to the Czechoslovak republic because of old age and invalidity insurance, which will be put into force, July 1. The clinic has an outpatient department and eighty-three beds equally divided between the sexes. The staff comprises two medical assistants besides the chief of clinic.

Directory

The Central Society of the Czechoslovak Physicians, which comprises all physicians of Czechoslovak nationality in the republic, has issued its directory. The society has obtained addresses of 4,539 Czechoslovak physicians, of whom 3,790, or 83.49 per cent, are regular members. There are about 8,000 physicians in the Czechoslovak republic, of whom 7,500 are practicing medicine. With a population of 13,500,000, this makes an average of one physician to 1,800 of population.

Tuberculosis Mortality

The figures for tuberculosis mortality in the Czechoslovak republic for the years 1923 and 1924 have been published. For all forms of tuberculosis the mortality for the country as a whole for 1923 was 190.2 per hundred thousand; for 1924, 190.05. The slight decrease is due chiefly to the statistics of pulmonary tuberculosis, while the mortality from other forms of tuberculosis remained almost constant. The decrease in tuberculosis mortality is limited to the western half of the Czechoslovak republic. The figures indicate that the western part of the republic, which is industrially developed, has passed its tuberculinization period and is building up a racial immunity coupled with an intensive campaign against tuberculosis. In the eastern part of the republic, where, until recently, the population lived under purely rural conditions, tuberculosis is spreading.

Marriages

Daniel W. Wheeler, Duluth, Minn., to Miss Della Hinshaw of River Forest, Ill., in April.

Hugh Cotter Boyle, Philadelphia, to Miss Evelyn A. Mallen of Conshohocken, April 10.

James Marsh M. Alesbury to Miss Mary C. Sullivan, both of Philadelphia, April 24.

Victor F. Cullen, Sabillasville, Md., to Miss Ethel Bell of Texas, May 19.

Deaths

Byron Clary Darling ⊕ New York; Medical School of Harvard University, Boston, 1903; member of the American Roentgen Ray Society and the Radiological Society of North America; assistant demonstrator of anatomy, Cornell University Medical College, 1903; formerly instructor in clinical orthopedic surgery, Columbia University College of Physicians and Surgeons; on the staffs of the Knickerbocker Hospital, 1904-1906, Lying-In Hospital, 1906, Bellevue Hospital, 1908-1910, St. Vincent's Hospital, 1909-1919, Ruptured and Crippled Hospital, 1912-1919, and St. Mark's Hospital, 1914-1925; aged 50; died, May 9, of pneumonia.

Edward Hickling Bradford ⊕ Boston; Medical School of Harvard University, Boston, 1873; member of the American Surgical Association; formerly professor of orthopedic surgery and dean at his alma mater; on the staffs of the Children's Hospital, 1878-1909, and the Boston City Hospital, 1880-1894, author of "Treatise on Orthopedic Surgery"; aged 77; died suddenly, May 7, of heart disease.

Alexander N. Stark ⊕ Colonel, U. S. Army, retired, Los Angeles; University of Virginia Department of Medicine, Charlottesville, 1892; was appointed assistant surgeon in the army in 1893 and retired with the rank of colonel, August 26, 1925, on account of physical disability; awarded the Distinguished Service Medal for his work during the World War; aged 56; died, May 8, at Hollywood, of angina pectoris.

Edward Hiram Abbott ⊕ Elgin, Ill.; Rush Medical College, Chicago, 1895; Spanish-American War veteran; for many years member and at one time president of the board of education; on the staffs of the Sherman and St. Joseph's hospitals; aged 59; died, April 12, following a long illness.

Lafayette Wallace Case, Colorado Springs, Colo.; Rush Medical College, Chicago, 1870; formerly lecturer in chemistry and dermatology at his alma mater; at one time on the staff of St. Joseph's Hospital, Chicago; aged 80; died, March 26, at Pasadena, Calif., of heart disease.

Alexander Douglas Wallace Kay, Detroit; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1911; member of the Michigan State Medical Society; served during the World War; aged 38; died, March 13, at a local hospital, of pleurisy.

Jirah H. Kellogg, Sterling, Colo.; University of Colorado School of Medicine, Denver, 1906; member of the Colorado State Medical Society; aged 54; died, April 17, of an overdose of a scopolamine-morphine mixture, self-administered for relief of pain.

Thomas F. McGlasson, Lewistown, Mo.; College of Physicians and Surgeons, Chicago, 1886; member of the Missouri State Medical Association; past president of the Lewis County Medical Society; aged 64; died, May 3, at the State Hospital, no. 1, Fulton.

William Graham Painter, Big Stone Gap, Va.; Medical College of Virginia, Richmond, 1901; member of the Medical Society of Virginia; aged 50; died, April 22, at the George Ben Johnston Memorial Hospital, Abingdon, of coronary thrombosis.

Charles E. Jenkins, Lynn, Mass.; Dartmouth Medical School, Hanover, N. H.; 1881; member of the Massachusetts Medical Society; one of the founders and formerly on the staff of the Union Hospital; aged 70; died, April 23, of heart disease.

Marion Herbert McGuire ⊕ New Orleans; Medical Department of the Tulane University of Louisiana, New Orleans, 1898; formerly instructor of anatomy at his alma mater; Spanish-American War veteran; aged 52; died, May 6.

Joseph Martin, Philadelphia; Jefferson Medical College of Philadelphia, 1878; member of the Medical Society of the State of Pennsylvania; for eight years member of the city council; aged 77; died, May 1, of heart disease.

Wilbur Gleason Ruble ⊕ Morristown, Tenn.; Kentucky School of Medicine, Louisville, 1904; past president of the Hamblen County Medical Society; served during the World War; aged 52; died, April 27, of heart disease.

Hyman M. Folkes ⊕ Biloxi, Miss.; Medical Department of the Tulane University of Louisiana, New Orleans, 1893; past president of the Harrison-Stone County Medical Society; aged 55; died, May 1, of cerebral hemorrhage.

Tarley William Jones, Fayette, Ala.; Vanderbilt University Medical Department, Nashville, Tenn., 1900; member of the Medical Association of the State of Alabama; aged 51; died, April 16, of pneumonia, following influenza.

Samuel Gibson Mugrage, Denver; Gross Medical College, Denver, 1895; formerly lecturer on clinical ophthalmology and otology and demonstrator of anatomy at his alma mater; aged 73; died, April 13, of heart disease.

Horace Clay Martindale ⊕ Pendleton, Ind.; Physio-Medical College of Indiana, Indianapolis, 1907; served during the World War; aged 45; died, May 4, at the Methodist Hospital, Indianapolis, of chronic nephritis.

James Glenn Donald, Pine Apple, Ala.; University of Alabama School of Medicine, Tuscaloosa, 1901; member of the Medical Association of the State of Alabama; aged 46; died, April 21, of angina pectoris.

Edward Skillman Hawke ⊕ Trenton, N. J.; University of Pennsylvania School of Medicine, Philadelphia, 1895; on the staff of the Mercer Hospital; aged 60; died, March 29, of acute dilatation of the heart.

Wilbur Fisk Shirkey ⊕ Charleston, W. Va.; College of Physicians and Surgeons, Baltimore, 1894; past president of the Kanawha County Medical Society; aged 67; died, March 29, of heart disease.

Harry Gilmore Carter ⊕ Burkeville, Va.; Medical College of Virginia, Richmond, 1914; superintendent of the Piedmont Sanatorium for eight years; aged 39; died, April 10, of pulmonary tuberculosis.

Harry S. Tuthill, Penn Yan, N. Y.; Jefferson Medical College of Philadelphia, 1881; aged 70; died, April 8, at the Soldiers' and Sailors' Memorial Hospital, following an operation for gastric ulcer.

George Henry Aiken, Fresno, Calif.; Medical Department of Columbia College, New York; 1869; Civil War veteran; for twelve years city health officer of Fresno; aged 81; died, April 12, of senility.

Israel Cleaver ⊕ Reading, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1863; Civil War veteran; aged 83; died, April 10, at the Reading Hospital, of arteriosclerosis.

John Wallace Hazen ⊕ Meadville, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1920; secretary, Crawford County Medical Society; aged 30; died, March 6, of pneumonia.

John A. Barnes, Tampa, Fla.; University of Georgia Medical Department, Augusta, 1891; member of the Florida Medical Association; for several years city physician; aged 58; died, March 1.

Early E. Scott, Fort Smith, Ark.; University of Louisville (Ky.) School of Medicine, 1908; member of the Arkansas Medical Society; served during the World War; aged 45; died, April 20.

William I. Sumner, Randleman, N. C.; University of Tennessee College of Medicine, Memphis, 1893; member of the Medical Society of the State of North Carolina; aged 56; died, May 6.

Robert Wilson Caldwell, Jackson, Ohio; Pulte Medical College, Cincinnati, 1895; member of the Ohio State Medical Association; aged 58; died suddenly, May 4, of cerebral hemorrhage.

Joseph W. Gregory, Cisco, Texas; Fort Worth School of Medicine, 1899; member of the State Medical Association of Texas; health officer; aged 57; died, April 12, of cerebral hemorrhage.

Albert Charles Zaiser, Santa Ana, Calif.; St. Louis College of Physicians and Surgeons, 1897; member of the California Medical Association; aged 52; died, April 11, of cerebral hemorrhage.

Joseph H. Delaney, Bozeman, Mont.; University of Virginia Department of Medicine, Charlottesville, 1897; aged 51; died, March 11, at San Antonio, Texas, of tuberculous meningitis.

Dargan Strother Pope, Columbia, S. C.; Jefferson Medical College of Philadelphia, 1875; member of the South Carolina Medical Association; formerly a druggist; aged 75; died, April 26

Ralph Howard Pulsifer, Belgrade, Maine; Hahnemann Medical College and Hospital of Philadelphia, 1890; Boston University School of Medicine, 1890; aged 60; died, March 5.

Elizabeth Hinckley Delavan, Troy, N. Y.; Cleveland Medical College, 1897; Boston University School of Medicine, 1898; aged 80; died, March 4, at Round Lake, of heart disease.

William Lafayette Henderson, Woodstock, Tenn.; Memphis Hospital Medical College, 1894; aged 53; died, March 2, at the Baptist Memorial Hospital, Memphis, of uremia.

Ernest William Baum ⊕ Phoenix, Ariz.; Rush Medical College, Chicago, 1895; aged 53; died, April 20, at a hospital in Hollywood, Calif., of uremia and chronic nephritis.

George Henry Denike, Bristol, Ind.; Hahnemann Medical College and Hospital, Chicago, 1905; aged 62; died, April 8, at the Epworth Hospital, South Bend, of heart disease.

James H. Hall, Pittsburgh; Leonard Medical School, Raleigh, N. C., 1906; member of the Medical Society of the State of Pennsylvania; aged 45; died, January 11.

Lorenzo D. Allard ⊕ Portsmouth, Ohio; Medical College of Ohio, Cincinnati, 1879; on the staff of the Portsmouth General Hospital; aged 70; died, April 8, of myocarditis.

Albert Martin Card, Head Tide, Maine; Medical School of Maine, Portland, 1875; member of the Maine Medical Association; aged 75; died, March 9, of pneumonia.

Frank Pierce Lyons, Flora, Ind.; Medical College of Indiana, Indianapolis, 1881; formerly county coroner; aged 73; died, April 26, of pernicious anemia.

James T. Hoskins, Washington, D. C.; Washington Homeopathic Medical College, 1894; formerly a druggist; aged 72; died, March 15, following a long illness.

William Edward Anderson ⊕ Farmville, Va.; Medical College of Virginia, Richmond, 1888; aged 59; died, May 10, at the Stuart Circle Hospital, Richmond.

Abraham L. Holloway, *Hutchinson, Kan.; Bennett College* of Eclectic Medicine and Surgery, Chicago, 1878; aged 68; died, April 9, of cerebral hemorrhage.

Frank David Paul, Rock Island, Ill.; State University of Iowa College of Homeopathic Medicine, Iowa City, 1886; aged 64; died, May 3, of pneumonia.

John William Craddock, Chicago; University of Illinois College of Medicine, Chicago, 1920; aged 31; died, March 9, following an operation for goiter.

Benjamin Thomas Fisher, Martinsville, Ind; Medical College of Indiana, Indianapolis, 1879; aged 79; died, May 1, at Spencer, of arteriosclerosis.

Samuel Harper Smith, McKeesport, Pa.; College of Physicians and Surgeons, Baltimore, 1881; aged 70; died, March 6, of carcinoma of the bladder.

Lisle W. Neiswender ⊕ Columbus, Ohio; Ohio Medical University, Columbus, 1906; aged 46; died, April 12, of heart disease, following influenza.

Harry Williamson ⊕ Marion, Ind.; Medical College of Indiana, Indianapolis, 1892; aged 61; died, April 12, at Miami Beach, Fla, of myocarditis.

William Franklin Taylor, Laurel, Md.; University of Maryland School of Medicine, Baltimore, 1884; aged 71; died, April 26, of heart disease.

James P. Driscoll, Spokane, Wash.; Northwestern University Medical School, Chicago, 1906; aged 44; died, April 6, of cerebral hemorrhage.

Samuel S. Hall, Jackson, Calif.; California Eclectic Medical College, Los Angeles, 1891; aged 59; died, March 5, of cardiovascular disease.

Carl Strueh ⊕ Chicago; University of Zurich, Switzerland, 1886; aged 64; died, May 6, at his home in McHenry, of cerebral hemorrhage.

Charles L. Gangloff, Pittsburgh; Cleveland University of Medicine and Surgery, 1892; aged 57; died, April 12, of pneumonia.

Ashton T. Ford, Sylvester, Ga.; Atlanta Medical College, 1889; aged 60; was killed, May 2, by an assailant.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE JOURNAL'S BUREAU OF INVESTIGATION, OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER GENERAL MATERIAL OF AN INFORMATIVE NATURE

CRESOG NOT ACCEPTABLE FOR N. N. R.

Report of the Council on Pharmacy and Chemistry

The Council has authorized publication of the following report

W. A. PUCKNER, Secretary.

Cresog (Cresog Laboratories Co, Detroit) is stated to be "composed of a pure glycerine base with the addition of two per cent of 'Pomcresol' (manufactured by Searle and Co., Chicago), plus Bicarbonate of sodium, 2%." The label and advertising for Cresog contain such meaningless statements regarding the composition as: "Derivative of Cresol, also Glycerine and Others" No information is given in regard to the composition of "Pomcresol."

Though the Cresog label admits that the preparation has a phenol coefficient of but 0.1, the preparation is claimed to have "strong germicidal effect." It is recommended on the label for "cuts, wounds, infections, sprains, inflamed joints and chapped hands," and it is stated that Cresog, used in the absence of a physician, "eliminates the possibility of infection."

The Council finds Cresog unacceptable for New and Nonofficial Remedies because its composition is indefinite, its name nondescriptive of its composition, the claims unwarranted, and the recommendations for its use such as may lead the public to place false dependence on it in serious conditions.

ROBES' ANTI-RHEUMATIC INJECTIONS NOT ACCEPTABLE FOR N. N. R.

Report of the Council on Pharmacy and Chemistry

The Council has authorized publication of the following statement.

W. A PUCKNER, Secretary.

Robes' Anti-Rheumatic Injections is marketed by Robes' Intravenous Products, Inc. In some of the advertising the synonym "Guaiamercol" is applied to the preparation. In Cuba this preparation is evidently called "Patogenol Gardier"

Robes' Anti-Rheumatic Injections is stated to contain mercuric chloride 0.9 mg, "guaiacum solids" 0.3 mg. and sodium chloride 0.0066 Gm. per cc. of 8 per cent alcohol.

The action of the "guaiacum solids" is not stated in the advertising or in the information submitted to the Council. The pharmacologic action is stated to be as follows:

> "When this solution is introduced into the system of an individual suffering from rheumatism, there is produced immediately the coagulation of certain heterologic albuminae, determining the formation of an *antigen* These coagulated albuminae, in the presence of the great mass in the blood stream, are dissolved and, at the same time, the injected solution continues to coagulate new groups of albuminae which, in turn, are dissolved in the blood stream. Thus, we have a real reversible reaction characteristic of the colloids, or a false catalysis, and this continues up to elimination through the natural emunctories The organism responds to the attack by producing the corresponding antibodies, which possess specific action against the bacteria and its toxins"
>
> "The affinity of the antibody for the causative organism is represented by reciprocal reactions, producing in that way the bacteriotropic and not the organotropic element This reaction is influenced by opsonic elements of the lipoid group, which favor the chemotactic between the antibodies and these bacteria"
>
> "In all cases where 'Robes' Anti Rheumatic Injections' are administered to a patient really suffering with rheumatism, general and local phenomena appear due to physico chemical reactions which determine the behavior of the heterogeneous albumins liberated"

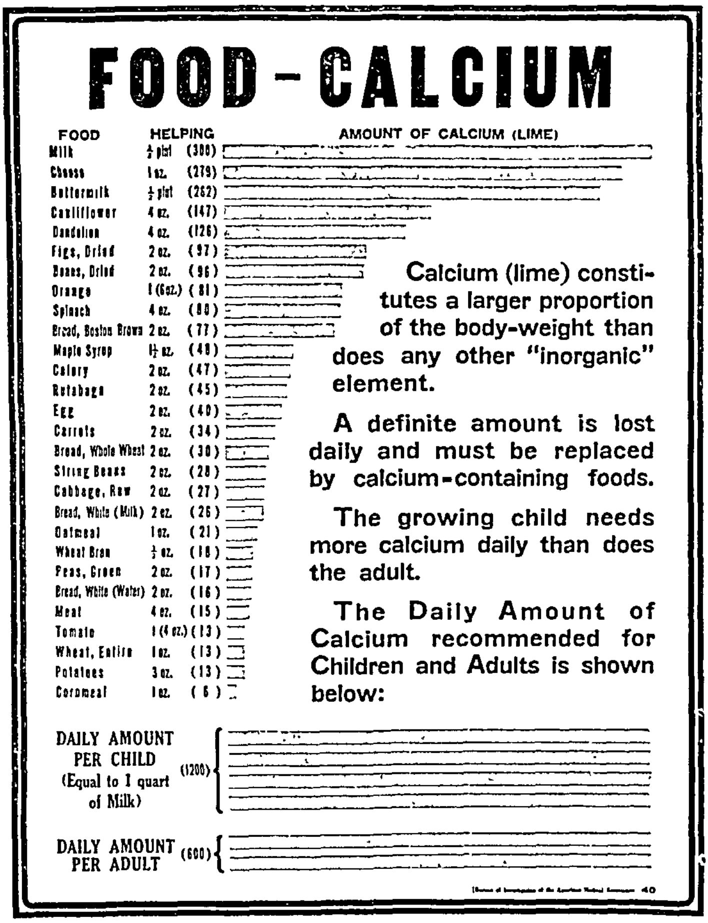
The therapeutic indications for Robes' Anti-Rheumatic Injections are stated to be:

> "In cases of Rheumatism, in any of its manifold manifestations: Sciatica, Lumbago, torticollis, facial neuralgia and iritis of rheumatic origin, visceral rheumatism, acute, subacute or chronic muscular or articular rheumatism, arthritis deformans, gonorrheal arthritis; post-measles or post scarlatinal arthritis. There are no counter indications. Its use is always beneficial due to its bactericidal action"

The circular which accompanies the trade package contains the additional information:

> "Sometimes in 15 to 20% of the cases, we notice that the patient does not respond to the medication; this is due to the fact that the 'chemical affinities' between the germs and the antibodies created by the introduction of our injections in the system, remain dormant. In such cases it is necessary to use the 'Lipoids' that we prepare from greasy vegetable acids, submitted to a special process that increases their vitality, and as we camphorate them, they act also as a tonic upon the heart, affected in most every rheumatic person."

The Council finds Robes' Anti-Rheumatic Injections unacceptable for New and Nonofficial Remedies because (1) its composition is indefinite in that no data are given as to the nature of "guaiacum solids"—which alone makes the preparation different from a simple solution of mercuric chloride in an alcoholic saline solution; (2) no tests are submitted whereby the "guaiacum solids" can be detected, or determined quantitatively; (3) the therapeutic claims are unwarranted, in that no evidence is submitted to show that "guaiacum solids" makes the preparation more effective than a simple solution of mercuric chloride or that the latter has any value in "rheumatism"; (4) the amount of the potent ingredient is not declared on the label; (5) the name is objectionable in that it does not indicate clearly the most potent ingredient and is therapeutically suggestive; (6) the trade package circular which accompanies the trade package advertises an unacceptable article and (7) because it is an unscientific preparation the use of which is detrimental to rational therapy.



Calcium (lime) constitutes a larger proportion of the body-weight than does any other "inorganic" element.

A definite amount is lost daily and must be replaced by calcium-containing foods.

The growing child needs more calcium daily than does the adult.

The Daily Amount of Calcium recommended for Children and Adults is shown below:

A miniature reproduction of a new poster just issued. This is one of forty educational posters prepared and issued by the Bureau of Investigation of the American Medical Association. The original posters are 22 inches by 28 inches, and sell for twenty cents each.

Correspondence

CARBON MONOXIDE FROM ILLUMINATING GAS

To the Editor:—The case of carbon monoxide poisoning reported by Dr. Stevens of New York in The Journal, April 17, impels me to call attention to my article published in The Journal in 1905 and entitled "The Dangers of the Domestic Use of Illuminating Gas and the Means of Avoiding Them." I served on the committee appointed by the College of Physicians, Philadelphia, to protest against large scale introduction of water-gas as an illuminant in Philadelphia. Newspapers and many citizens jeered at the protest, but the subsequent fatality record is evidence of the danger of gas highly charged with carbon monoxide. The "slot-meter" in which a coin automatically starts the flow of gas has added new danger. Frequently these meters are broken open by thieves and the gas is allowed to escape.

Henry Leffmann, M.D., Philadelphia.

"WHO'S WHO IN AMERICAN MEDICINE"

To the Editor:—About a year ago I was circularized re "Who's Who in American Medicine." Without much thought I filled in the blank as one would the questionnaire of the A. M. A. Directory, and later canceled the order. I now realize the folly of such a publication coming from a commercial publishing company. The publishers insisted on mailing a copy, which I refused at the post-office. Since then I have had two bills and several letters insisting that I must take the book on "moral grounds."

There is no need of such a publication that cannot be better filled by our own directory. I ask, How is any one to judge who is who anyway? What special talent is to decide?

F. J. Walter, M.D., La Mesa, Calif.

CUTIS VERTICIS GYRATA

To the Editor:—In The Journal, April 10, p. 1126, Dr. Raymond J. Sisson, in discussing cutis verticis gyrata, states that "only a few cases have been reported, and none were associated with acromegaly." In the article on acromegaly in "Endocrinology and Metabolism" (edited by Barker and Hoskins) **1**:831, two cases of cutis verticis gyrata in acromegaly are quoted, one reported by Sabat, the other by C. Adrian. I have seen one case in an acromegalic woman, but this case has not been reported.

Peter Bassoe, M.D., Chicago.

"CRYSTALLINE PROTEINS IN URINE"

To the Editor:—In The Journal, May 1, Welker, Thomas and Hektoen (p. 1333) state that "crystalline proteins have been isolated from the urine up to the present time in only eight cases." Dr. D. Wright Wilson (*J. Biol. Chem.* **56**:203 [May] 1923) described a spontaneously crystallizable protein of a Bence-Jones nature. Other references of interest in this connection are: *J. Biol. Chem.* **18**:277, 1914, and *J. Physiol.* **42**:199, 1911.

Withrow Morse, Philadelphia.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed Every letter must contain the writer's name and address, but these will be omitted, on request.

RAT VIRUS

To the Editor.—There is being sold in considerable amounts a substance called Azoa, which is used for killing rats It is said to be harmless except for killing rats. Can you give me any information about it? I am particularly interested because I know of instances in which it has been used around camps in the woods and on water courses which might drain down into a fairly thickly populated community which obtain their water from the river.

FRITZ B TALBOT, M D, Boston

ANSWER—Azoa, like other preparations of this type, contains a rat virus which is a bacterium belonging to the paratyphoid group of bacilli. Organisms of this group have been associated with outbreaks of gastro-enteritis or food poisoning. The group contains a number of species of bacteria which vary considerably in their pathogenicity toward man and animals. Manufacturers of rat viruses maintain that they are harmless for human beings. Epidemiologic evidence involving these viruses in outbreaks of paratyphoid infection has certainly not been frequent. Wade and McDaniel (THE JOURNAL, Nov. 1, 1924, p 1416), in describing a milk borne outbreak with simultaneous but apparently unrelated increased incidence of the disease in Minneapolis, state that they found no evidence that would involve rat viruses. On the other hand, Spray (THE JOURNAL, Jan 9, 1926, p. 109) has produced evidence to connect the use of a rat virus with a food poisoning outbreak. Contamination of a raw water supply or of food by organisms of the paratyphoid group, whatever their origin, would appear to involve some risk.

HAZARDS OF LAMP SHADE INDUSTRY—PREVENTION OF LEAD POISONING

To the Editor.—1. What special hazards are to be encountered in the manufacturing of lamp shades? The coloring of these shades is done by spraying various paints over prepared parchment It appears that amyl alcohol is the usual solvent for the staining materials The question has arisen as to the injurious effects of such volatile matter as might be contained in these preparations 2 Are there any drugs or chemicals that might be added to drinking water to render it an efficient prophylactic against daily exposure to lead poisoning? In the literature, a mild acid drink, such as lemonade, seems to be generally favored In the particular plant where this lead hazard is to be found, the men work only six hours a day It is a question whether it would not be more advisable to favor the daily excretion of lead absorbed during that period rather than favor the storage of such in the bones, such as is usually done on a high calcium diet. Please omit name.

M D., California

ANSWER—1. On all sides lamp shades may be seen, made of art glass, fabrics, pottery ware, reed and paper. Our correspondent refers only to the hazards incurred in the making of shades from paper. The processes involved are continually changing; no uniformity exists in this industry. The cheaper imitation parchment papers are given a coating of tinted shellac The solvent is commonly denatured ethyl alcohol. At present there is a vogue for shades studded with glass particles or glass beads. In this process the fixative is made of resins and wax dissolved in denatured alcohol. The pigments are likewise dissolved or suspended in this mixture of resins and alcohol. In still other factories lacquers are employed in which benzene, benzine, amyl alcohol, amyl acetate or tetrachlormethane may be used. It is from this group that intoxications may be expected Benzene in particular should not be employed in such spray methods without adequate means for eliminating fumes; i. e, through the use of booths with suction.

If the workers are affected by amyl alcohol (fusel oil), some or all of the following manifestations may arise: vomiting, dizziness, great weakness, slowing of heart rate, shortness of breath, severe headache or low blood pressure. If benzene is responsible for the intoxications, some or all of these manifestations may arise: slight inflammation of the conjunctiva and respiratory tract, pain in the abdomen, frequent urination, headache or muscle tremors; occasionally a very susceptible person will quickly become unconscious and die without any preliminary symptoms or signs; in chronic cases, hemorrhage into the skin and from the gums, lungs, stomach or genitalia is characteristic, together with anemia, leukopenia and loss of blood platelets. A more complete description of the toxicity of benzene, with references, was given in THE JOURNAL, Oct. 3, 1925, p 1081 Most of the solvents now in common use as thinners and in lacquers and varnishes will produce severe dermatitis, usually on the hands and forearms.

2 The addition of any substance to the drinking water supply of workers exposed to lead is not at this time regarded as a practical step in the prevention of lead poisoning Previously, weak sulphuric acid lemonade or lemonade containing magnesium sulphate was recommended in the belief that lead sulphate would be formed and that this salt would be insoluble in the gastro-intestinal fluids While lead sulphate is less soluble, it is to some extent taken up by the intestinal tract. Much lead poisoning is produced by lead entering the body by way of the respiratory tract Obviously, any treatment of the water supply would not protect against this mode of entry.

High calcium or other alkali intake favors the fixation of lead in the body tissues, with a resulting freedom from clinical lead poisoning It is not known, however, whether or not this is merely putting off the eventuality of lead poisoning when later the hydrogen ion concentration is altered through the omission of alkalis It is regarded as a safe procedure to encourage lead workers to utilize a high calcium diet, to take alkalis at frequent intervals, and then about once a year to eliminate the stored lead through the administration of such chemicals as ammonium sodium chloride, iodide or ammonium acetate Best of all is the elimination of the hazard itself through the control of lead dusts and fumes, and the education of workers to avoid the entry of lead into the mouth from the hands, cigarets or food

IODINE FOR GOITER—FELLOWSHIP AND MEMBERSHIP

To the Editor—1 Please set me right on when and when not to give iodine in goiter Recently a friend had iodine administered, and there was considerable argument pro and contra In hypothyroidism, thyroid extract is administered, yet I see that Crile and others give thyroid extract or iodine preparatory to removal of the gland. It is the iodine in the thyroid extract that produces the results, if I understand it right Then why give thyroid extract or iodine in both conditions? What is the consensus regarding the roentgen ray in goiter? One man says yes another says no, so it puts one where he does not know how to advise his goiter patients From the journals and in conversation with different men it is just as perplexing I have given iodine in hyperthyroidism and got fairly good results The foregoing may sound more or less puerile but I just cannot see where the thyroid extract comes in in hyperthyroidism 2 What is the difference between a member of and a Fellow of the American Medical Association?

HERMAN CASTILE, M D, Foreman, Ark.

ANSWER—1 Many of the rest of us are at times as puzzled as is our correspondent concerning the proper procedure in certain cases of hyperthyroidism, but not all of us are as frank in admitting our difficulties. The reasonable inference to be drawn from the conflicting evidence is that there is still much to be learned about the thyroid and its functions, and that the question of treatment is not nearly so simple as some would have us think We are advised to give iodine in exophthalmic goiter and warned against giving it in toxic goiter While there is no great difficulty in placing some cases in one and some cases in the other of these two groups, there are many cases in which this classification is difficult, and for many of us impossible on clinical grounds. Whether iodine should be used in these doubtful cases may in some instances be determined only by cautious trial. In recent years, attention has been repeatedly called to the appearance of symptoms of hyperthyroidism in persons who have been given even small doses of iodine. In hyperthyroidism the signs and symptoms, such as tachycardia, nervousness, tremor, loss of weight or increased metabolic rate, appear in widely differing degrees in different cases, and the question may well be raised as to the possible multiplicity of thyroid hormones, overfunction of one or more of which may account for the variability of the clinical picture. There is no consensus as to the value of the roentgen ray in hyperthyroidism. Some patients improve remarkably following a series of roentgen-ray treatments. In others, the results are disappointing Ligation and roentgen ray together are sometimes effective Partial and subtotal thyroidectomy are required in others In estimating the value of any one of these procedures, we are often inclined to forget that overacting thyroids pass through cycles of overaction and relative quiescence, independently of treatment.

2 All members, in good standing, of state medical associations whose names are reported to the American Medical Association for enrolment are members of the American Medical Association. All members of the American Medical

Association in good standing are eligible for Fellowship. To qualify as a Fellow, a member is required to make formal application and to subscribe to The Journal. Fellowship dues and subscription to The Journal are included in the one annual payment of $5. None but Fellows can serve as officers or delegates, and none but Fellows and invited guests can participate in the work of the sections of the Scientific Assembly.

TREATMENT OF INFECTION OF THE ANTRUM

To the Editor:—Will you please outline for me the recognized modern treatment of an infection of the antrum of Highmore, whether or not to be irrigated through a tooth socket opening; if so, how often and what solution used? Whether or not a window operation through the nose is the thing? Whether vaccines would be of value, whether physiotherapy (quartz) is curative, or, if of value, how much can be depended on it alone? Any further suggestions as to treatment will be appreciated.

Roland R. Cross, M.D., Dahlgren, Ill.

Answer.—Infections of the antrum of Highmore, or maxillary sinus, are usually treated by irrigation or, if necessary, by direct drainage. There are three routes by which the antrum may ordinarily be irrigated. First, by way of the natural opening in the middle meatus. This merely requires cocainization of the middle meatus and then the passing of a cannula into the natural opening or into one of the accessory openings. Second, there is the route most often used by way of the inferior meatus. After thorough cocainization, a trocar is pushed through the inner wall of the antrum, which is the outer wall of the nose, and the sinus thus entered. The third route is by way of the alveolar process, usually through a socket of the upper second bicuspid or first or second molar. No good tooth should be sacrificed in order to enter the antrum this way. In the second place, if a tooth has for some reason or other been removed, it is possible by means of a hand or electrically driven drill to open into the antrum. However, we believe the last route the least desirable, as it is almost impossible to prevent reinfection of the antrum from the entrance of saliva or food particles through this opening into the cavity.

In acute cases, a warm physiologic sodium chloride or mildly alkaline solution, such as 2 or 3 per cent sodium bicarbonate, is usually best. For the subacute or more chronic cases, solutions such as 1: 2,000 or 1:3,000 copper sulphate may be employed. If the irrigations do not suffice in the acute or in the chronic cases, operative procedures are sometimes necessary and the various routes previously mentioned may be used. We may enlarge the natural opening in the middle meatus or, preferably in order to get better drainage, do a window resection in the inferior meatus, making as large an opening as possible. In some cases a more radical operation, such as the Luc-Caldwell or Denker, is required in very chronic or obstinate instances. Vaccines are as a rule of value only when thorough drainage has first been established. Physiotherapeutic measures, such as the quartz lamp treatment or diathermy, have not given very definite curative results, so far as we know. An important measure for prophylaxis or cure is the removal of any upper teeth, especially the second bicuspid or first or second molars, which show infection of the apexes. If not removed, these teeth very easily produce infection of the maxillary sinus. In any case, we believe that conservative measures, such as irrigation or minor operations, should be employed before any radical procedure is instituted.

TREATMENT OF WOUNDS

To the Editor:—In minor industrial accidents, is it now considered good practice to wash blood off injured surface with an antiseptic solution, or to dress the injury without doing this? Please use initials.

R. W. C., M.D., New Jersey.

Answer.—If there is any considerable amount of blood, it should be washed off. If the blood has dried and is crusted, a liquid composed of solution of hydrogen dioxide and water, equal parts, quickly removes this. The small wound should then be painted with tincture of iodine or a 2 per cent solution of mercurochrome-220 soluble, and a dry dressing applied.

TREATMENT OF PINWORMS

To the Editor:—I was interested to see Dr. Hollingsworth's inquiry regarding the treatment of pinworms (The Journal, April 24, p. 1309). Long residence in the tropics, where all varieties of intestinal parasites are encountered, has led me to rely on massive doses of bismuth carbonate. For an adult, we give from 1 to 2 drachms (4 to 8 Gm.) night and morning for three days.

H. P. Nottage, M.D., Albany, Ore.

The Surgery of Pulmonary Tuberculosis. By John Alexander, B.S., M.A., M.D., Assistant Professor of Surgery in the Medical School, University of Michigan. With introductions by Hugh Cabot, M.D., C.M.G., LL.D., Professor of Surgery, University of Michigan, and Edward R. Baldwin, M.A., M.D., Director of the Trudeau Foundation and Trudeau School of Tuberculosis. Cloth. Price, $4.50. Pp. 356, with 65 illustrations. Philadelphia: Lea & Febiger, 1925.

This is the most complete monograph that has yet appeared in the English language on the subject. It is an ideal contribution to the literature, as it is scholarly, orderly and complete, and condenses into a small volume the present knowledge of the subject. The author points out that few physicians and surgeons are yet aware that surgery is now curing or improving approximately two thirds of those selected cases of far advanced pulmonary tuberculosis that other methods of treatment have failed to benefit. The material covered includes a perspective of the surgery of pulmonary tuberculosis; evolution of surgical therapy, pathologic anatomy and physiology of pulmonary compression; indications and contraindications for surgical intervention; artificial pneumothorax compared with thoracoplasty; choice of operation; partial operations; preoperative management; choice and technic of anesthesia; the Wilms-Sauerbruch extrapleural paravertebral thoracoplasty; the Bauer subscapular extrapleural paravertebral thoracoplasty; paravertebral thoracoplasty of the upper seven ribs compared with radical phrenicotomy; extrapleural parasternal thoracoplasty; partial artificial pneumothorax combined with partial paravertebral thoracoplasty; phrenicotomy; extrapleural pneumolysis; Jacobæus' closed intrapleural pneumolysis; open intrapleural pneumolysis; drainage of the tuberculous lung cavity; spontaneous pneumothorax; tuberculous effusion and empyema; postoperative course and management, including complications; changes in configuration of the chest following thoracoplasty, and the results of paravertebral thoracoplasty. There is a bibliography which is practically complete for the years 1918-1924, inclusive, with the titles of a number of articles appearing early in 1925 and several references of historical importance dated prior to 1918.

Alexander prefers thoracoplasty to artificial pneumothorax. In discussing preoperative preparation, he approves the use of digitalis to strengthen the heart. In general, he prefers the Wilms-Sauerbruch extrapleural paravertebral thoracoplasty to the other methods of thoracoplasty, although in certain cases other methods of thoracoplasty may be employed, or extrapleural pneumolysis, or, in rare cases, the drainage of cavities. In considering Jacobæus' closed intrapleural pneumolysis Alexander concludes, as in the chapter dealing with artificial pneumothorax compared with thoracoplasty, that unless artificial pneumothorax can be undertaken and completed under favorable conditions, thoracoplasty offers the patient a better prognosis. If a satisfactory pneumothorax cannot be obtained by a relatively simple operation of short duration, both cauterization and pneumothorax should be abandoned and thoracoplasty performed. Sauerbruch considers ether the anesthetic of choice, and his experience on many hundreds of patients with active pulmonary tuberculosis has convinced him that it has no unfavorable action on the lungs, unless by abolishing the cough reflex it allows aspiration of secretions. This opinion as to the relative harmlessness of ether in the presence of pulmonary tuberculosis is not in accord, however, with the general belief and practice. Many thoracic surgeons in this country prefer to combine procaine-epinephrine local anesthesia with nitrous oxide-oxygen anesthesia. Alexander believes that local anesthesia in conjunction with ethylene gas anesthesia is probably the best anesthetic available for the surgery of pulmonary tuberculosis, except in patients with more than 30 cc. of sputum a day and those to whom a general anesthetic per se would be dangerous. In the latter cases, local anesthesia alone should be used.

In considering the Wilms-Sauerbruch operation, as in the various chapters dealing with other operative procedures, the author begins with a definition, and then discusses the operation in the minutest detail, including the position of the patient on the table, the position of the surgeons, the incision, the use of wound protectors, and the order of rib resections. In explaining the technic for subperiosteal rib resection, he describes and illustrates his ingenious rib-edge periosteum stripper, which will strip the rib edges rapidly, cleanly and without danger of wounding the pleura. Other surgeons have spoken highly of this instrument and agree with the author that it renders easy the separation of the periosteum from the edges of the ribs beneath the tenacious attachment of the intercostal muscles, a step that is often tedious and must be done slowly in order not to injure the pleura. Alexander regularly resects the most prominent rib first. This is usually the ninth; then follow the eighth, seventh, sixth, fifth, tenth and eleventh. This concludes the first stage if a two-stage operation is performed, which is the rule. The second stage should be done within six weeks of the first as a rule, because in from six to eight weeks after the first stage there is regeneration of rib from the remaining periosteum, often with bony bridging between the ribs, and with more or less rigid fixation of the chest wall. At the second stage, the upper four ribs are resected in this order: fourth, third, second, first. Most surgeons prefer an interval of from two to three weeks. The length of the various ribs to be resected is discussed in detail. Supplementary operations, which at times are necessary, are briefly summarized. The important points of the Wilms-Sauerbruch operation include the subperiosteal resection of sufficient lengths of the eleventh to the first rib, inclusive, from below upward, in two stages; removal of ribs beginning from the tips of the transverse processes of the vertebrae; careful avoidance of wounding the pleura; speed in operating; an interval of from two to three, but not more than six, weeks between stages. If the tuberculous lesions, especially cavities, are insufficiently compressed and rested six months after the operation, one or more of the following supplementary operations may be indicated: phrenicotomy, secondary paravertebral resections, extrapleural parasternal thoracoplasty, extrapleural pneumolysis with "filling," or cavity drainage. Alexander believes that doubt may justly be expressed as to the wisdom of resecting the lower ribs at the first stage of the operation because of the danger consequent on the impairment of expectoration, and that phrenicotomy as a substitute for primary resection of the lower ribs will probably reduce the operative mortality and postoperative lung complications.

The author states that surgery has favorably influenced 61.2 per cent of the patients reported as operated on during the past seven years and has actually cured 36.8 per cent of them. All were in far advanced stages of the disease, most had cavity formation, and many had bilateral active lesions. They were referred for operation because the prognosis was considered hopeless without surgical intervention. The extent to which these results can be bettered depends on the widespread use of the improvements that are being made in operative technic and in preoperative and postoperative management, and particularly in the proper selection of patients for surgery. The author has contributed this volume in the hope that in the future operation frequently will be performed while the patients are in good general condition and while the lesions are almost entirely limited to one lung.

Handbuch der Hals-Nasen-Ohren-Heilkunde. Mit Einschluss der Grenzgebiete. Herausgegeben von A. Denker und O. Kahler. Zweiter Band. Zweiter Teil. Die Krankheiten der Luftwege und der Mundhöhle. Paper. Price, 84 marks. Pp. 1068, with 394 illustrations. Berlin: Julius Springer, 1926.

This is the second volume of this encyclopedic work on the ear, nose and throat, and covers the subject of the respiratory tract and the oral cavity. The volume opens with a continuation of the pathology and therapy of the nose from the previous volume. Under the heading of therapy, many general measures of prophylactic and active nature are given. Many details are presented under the heading of anesthesia, both general and local. A number of the new preparations for local anesthesia are mentioned. The chapters on operative technic include tracheotomy. Under the next heading there is a complete discussion of malformations of the nose, mouth, pharynx and larynx. The chapter on diseases of the nasal septum is well illustrated, and tells about the various methods that have been used in operations for the correction of deflections. Under the next heading there is a discussion of acute and inflammatory conditions involving the nose and nasal accessory sinuses, with the various cranial complications that arise from these conditions. This volume is a good companion to the preceding one, it is complete, has a detailed bibliography, presents numerous illustrations, and contains a world of facts.

Public Health Law A Manual of Law for Sanitarians. By James A Tobey, M S, LL B, Lecturer on Public Health Law at the Massachusetts Institute of Technology, Yale School of Medicine, and Columbia University Cloth Price, $4 50 Pp 304 Baltimore The Williams & Wilkins Company, 1926

Within the compass of 239 pages, exclusive of four appendixes and a table of cases, the author outlines the organization and powers of health departments, state and local, and devotes one chapter each to the control of communicable diseases, to the abatement of nuisances, to venereal diseases, to the legal aspects of mental hygiene, to the legal liability for damages arising out of public health activities, and to the drafting of health legislation In early chapters the author discusses the basis and importance of public health law. The value of the book is chiefly in its general information and in its references to sources from which further information can be obtained. In compiling and arranging the references, the author has rendered a pioneer service. In addition to the numerous citations to adjudicated cases, a selected bibliography is included as one of four appendixes, the references being divided into three groups: (1) those pertaining to public health in general; (2) those relating to law without particular reference to public health, and (3) those referring to public health law. The book, according to the preface, while designed especially for health workers, "may likewise prove of value to jurists, lawyers, government officials, physicians, sociologists, students, and others who may be called on to delve into the administration of sanitary science." It has in it little of peculiar value to the physician.

Die Innervation der Harnblase. Physiologie und Klinik. Von Dr Med Helmut Dennig, Assistent der medizinischen Klinik Heidelberg Privatdozent fur innere Medizin. Paper. Pp. 98, with 13 illustrations. Berlin: Julius Springer, 1926

This is a welcome addition to the subject of the normal and pathologic physiology of the bladder. Assembled here is a critical survey of all the literature on the function and innervation of the vesical musculature, sensibility of the bladder, and the relations of the normal act of micturition to higher centers in the spinal cord and brain. A number of instructive experiments made by the author are reported. The chapters on disturbances (both organic and functional) in the act of urination will be of especial value to the internist, neurologist and urologist. The book can be warmly recommended as the best monograph so far published on the subject.

Bacteriology and Applied Immunology for Nurses By Robert A. Kilduffe, A B, A M, M D, Director, Laboratories, Atlantic City Hospital Leather Price, $2 Pp. 252, with 79 illustrations Milwaukee: Bruce Publishing Company, 1926.

Those who have attempted to teach a course in bacteriology to nurses will appreciate the difficulties involved, particularly that of the very brief time allowed for laboratory work. A specially prepared textbook should be of service for such instruction, and Dr. Kilduffe's little volume is the latest to be made available. The book is attractively printed and fully illustrated, is written in simple language, and will undoubtedly be used. It is not evident why the discussion of practical applications of immunity belongs in the general section of "Bacteriology," while water and milk examination are found under "Applied Immunology"

Books Received

Books received are acknowledged in this column, and such acknowledgment must be regarded as a sufficient return for the courtesy of the sender. Selections will be made for more extensive review in the interests of our readers and as space permits.

Correcting Speech Defects and Foreign Accent. By Grace A. McCullough, Supervisor of Speech Improvement in the New York City Schools, and Agnes V. Birmingham, in charge of Speech Improvement in the New York City Schools. Cloth. Price, 88 cents. Pp 232, with illustrations New York: Charles Scribner's Sons, 1925.

Practical and suggestive textbook of great interest to physicians who may be asked to advise in cases of speech defect.

A Classification of the Tumors of the Glioma Group on a Histogenetic Basis with a Correlated Study of Prognosis. By Percival Bailey and Harvey Cushing From the Surgical Clinic and Laboratory of the Peter Bent Brigham Hospital and the Laboratory of Surgical Research of the Harvard Medical School. Cloth Price, $5 Pp 175, with 108 illustrations Philadelphia. J. B. Lippincott Company, 1926

A monographic record of technical research under good auspices.

Physics and Chemistry for Nurses. By A. R. Bliss, Jr, A M, Phm D, M D, and A H. Olive, A M, Ph C.H., Phm.D. Fourth edition. Cloth Price, $2 50 Pp. 190, with 20 illustrations Philadelphia: J. B. Lippincott Company, 1926

Much more information than a nurse can learn or use, but conforms to the standard curriculum of the National League of Nursing Education

Simplified Infant Feeding: With Eighty Illustrative Cases By Roger H Dennett, B S, M D, Professor of Diseases of Children and Director of the Department in the New York Post Graduate Medical School Third edition Cloth Price, $5 Pp. 415, with 14 illustrations Philadelphia J B Lippincott Company, 1926.

New edition with additional material on acidified milk, calcium caseinate, vitamins, gelatin, and similar new subjects.

The Aspergilli. By Charles Thom and Margaret B Church of the Microbiological Laboratory, Bureau of Chemistry, United States Department of Agriculture By G L Keenan Cloth Price, $5. Pp 272, with illustrations Baltimore: Williams & Wilkins Company, 1926

Complete information concerning molds, with a key to their identification.

Our Minds and Their Bodies By John Laird Regius Professor of Moral Philosophy in the University of Aberdeen. Cloth. Price, $1. Pp 122 New York: Oxford University Press, 1925

Well written lecture giving modern philosophic conceptions of relations of mind to body.

Your Hair and Your Health. By Oscar L. Levin, M.D, Chief of Clinic Cornell University Medical College and Clinic. Cloth Price, $1 50 Pp 163, with 10 illustrations New York: Greenberg, 1926

Guidebook written in popular tone but with some popular fallacies.

The Proceedings of the Charaka Club. Volume VI Boards. Price, $4 Pp 145, with Illustrations New York: Paul B. Hoeber, Inc, 1925

Medical belles-lettres of a charming type, reflecting the esthetic aspects of the art and practice.

Diseases of the New-Born: A Monographic Handbook. By John A. Foote, M D, Professor of Diseases of Children, Georgetown University Medical School Cloth Price, $5. Pp 231, with 85 illustrations. Philadelphia. J. B Lippincott Company, 1926.

Brief practical essays, well illustrated.

The Further Studies on Decrementless Conduction. By Genichi Kato, Professor of Physiology, Medical College, Keio University, Tokyo. Cloth Pp 163, with 88 illustrations Tokyo, 1926

Technical research on energy of nerve impulse.

Mortality Statistics, 1923. Twenty-Fourth Annual Report. Department of Commerce Herbert Hoover, Secretary. Bureau of the Census, W. M Steuart, Director. Cloth Price, $1.50. Pp. 485. Washington: Government Printing Office, 1926

Collected Papers By the Staff of the Henry Ford Hospital. First Series, 1915 1925 Cloth Price, $8 Pp 634, with 193 illustrations. New York: Paul B. Hoeber, Inc, 1926.

Medicolegal

Liability of Private Hospital—Regarding Physicians

(Vaughan v. Memorial Hospital (W. Va.), 130 S. E. R. 481)

The Supreme Court of Appeals of West Virginia, in affirming an order setting aside a verdict rendered for the plaintiff and awarding the defendant a new trial, says that the plaintiff sustained an injury to his right foot, two bones near the first and second joint of the second and third toes being broken. Two days later he was taken to the defendant hospital for treatment. After his discharge the foot became swollen and painful. A roentgenogram disclosed that the bones were not knitted, and they were subsequently removed. The defendant contended that it was not responsible for any default on the part of the physicians, they being independent agents. But a hospital incorporated and conducted for private gain, for the benefit of its stockholders, is liable in damages to its patients for negligence or misconduct of its officers and employees. The purely private character of the defendant was practically admitted. The capital invested is like capital invested in any other corporation conducted for profit. In its contracts it stands on the same basis as any other contractor, and as to employees and third persons, it is subject to the same general rule, respondeat superior (let the master answer). The plaintiff and the defendant were brought into relation with each other through the agency of the employer of the former, and he received the surgical and medical care to which he was entitled under the rules and regulations of the state compensation commissioner, the expense thereof to be paid out of the workmen's compensation fund. The application to the commissioner for payment of the medical, surgical and hospital treatment was rendered in the name of the defendant, and included the item for the operation on the plaintiff's foot by the two physicians before referred to. Moreover, it appeared in evidence that those physicians were the managers of the hospital, and that the roentgen-ray machine used in the hospital for the examination of the plaintiff's injury was the property of the institution. Under these conditions, authorities cited hold that the defendant could not absolve itself from the obligation it owed to the plaintiff patient to furnish him proper treatment, on the claim that the physicians who treated him, at its instance, were independent contractors. In view of this, the trial court erred in submitting the question of whether the medical and surgical treatment was rendered the plaintiff by the physicians on their own account, in an instruction given to the jury at the instance of the defendant.

This court thinks that it may be said to be the generally accepted doctrine that a physician is not required to exercise the highest degree of care or skill and diligence possible, in the treatment of an injury, or disease, unless he has by special contract agreed to do so. In the absence of such special contract, he is only required to exercise such reasonable and ordinary skill and diligence as are ordinarily possessed and exercised by the average of the members of the profession in good standing, in similar localities and in the same general line of practice, regard being had to the state of medical science at the time. The general rule just stated does not make the physician in any sense a warrantor or insurer of the success of his treatment, in the absence of a special contract to that effect. And where a physician exercises ordinary skill and diligence, keeping within recognized and approved methods, he is not liable for a mere mistake of judgment. However, he is liable for the result of an error of judgment, when such error is so gross as to be inconsistent with that degree of skill which it is the duty of a physician to possess.

The bones taken from the plaintiff's foot were introduced, but the trial court refused to permit them to go in evidence to the jury for lack of being properly identified. The physician who took them from the foot was not introduced as a witness, nor was his deposition taken. His absence was not accounted for. He unquestionably possessed peculiar knowledge concerning facts vitally essential to the plaintiff's case—the condition of the bones when removed, what caused the condition, and whether there was pus present. The circuit judge doubtless thought this testimony should have been offered. He has a discretion to exercise when a case has not been fully developed. He may set aside the verdict to do justice to all parties. This court cannot say he abused that discretion in this case. If the testimony of the physician who removed the diseased bones was material to the plaintiff's case, and he wished to avoid the effect of the legal presumption that, if the physician had testified, his testimony would have been adverse to him, he should have shown proper diligence to have the physician present as a witness, or have taken his deposition.

Good Indictment of Chiropractor

(Robinson v. State (Ala.), 106 So. R. 53)

The Court of Appeals of Alabama, in affirming a judgment of conviction of defendant Robinson, says that the case was tried on the first two counts of the indictment, to which demurrer was interposed. Those counts charged that the defendant did treat or offer to treat diseases of human beings by a system known as chiropractic for a reward, without first having obtained a certificate of qualification from the state board of medical examiners of the state of Alabama and contrary to law; and further charged that he did treat or offer to treat diseases of human beings by a system known as chiropractic for a reward, such a system being practiced by men known as chiropractors, without first having obtained a certificate of qualification from the state board of medical examiners of the state of Alabama, contrary to law. These counts were demurred to on the ground that they did not sufficiently describe the system by which the defendant was averred to have treated or offered to treat disease; that they failed sufficiently to describe the alleged system known as chiropractic or what was done by chiropractors, or to aver that it was unknown. But the two counts sufficiently charged the offense and were not subject to the demurrers interposed. The Alabama statute is designed to prevent the treatment of diseases of human beings by any system whatever, without the party so engaged having first obtained a certificate of qualification from the state board of medical examiners of Alabama.

"Shell Shock"—Doubt as to Sanity of Defendant

(People v. Gilberg (Calif.), 240 Pac. R. 1000)

The Supreme Court of California, in holding that the trial court had not abused its discretion by omitting to suspend the trial of the defendant for a lewd act, to submit the question whether or not he was then insane, says that he had served in the World War. He received no battlefield wounds, but insisted that he had suffered an injury by falling into a "funk-hole." It appeared that he had spent considerable time as a patient in hospitals under treatment for "shell shock." "Shell shock" is not a distinct type of nervous disorder, but a condition produced on certain organisms by sudden fear or by highly exciting causes. It is a form of neurosis. It is not settled, general insanity, but, according to the testimony of the expert offered by the defense, a functional nervous disease, and not due to organic changes.

The existence of a doubt as to the sanity of a defendant means, of course, any doubt that may be created in the mind of the trial court arising from a consideration of all the facts and circumstances which the situation may disclose, and he may, on his own motion, in the exercise of a sound discretion, submit the question of the defendant's sanity to the determination of a jury. Such a doubt must be supported by facts and circumstances of a substantial character. This right does not arise merely because the defendant asserts insanity, however baseless the assertion may be. To justify the dismissal of the jury or the suspension of a trial, the court must entertain a doubt founded on substantial grounds. In other words, there must exist reason to believe that the claim of insanity made on behalf of the accused is genuine and not simulated as a means of defeating or delaying the law's penalties in cases in which all other means of evading punishment would seem hopeless. The question of whether a doubt sufficient to require the trial court to submit the issue of the sanity of a defendant to a jury during trial is one that must always rest largely within the discretion of the trial court. On principle, the question is not unlike the discretion which the law reposes in a court when it is called on to pass on the competence of witnesses to testify as to the sanity of persons generally.

For insanity to be available as a defense to crime, it must be shown by a preponderance of the evidence that the accused did not know the nature or the quality of the act which he committed, or, if he did know the nature and quality of the act, that he did not know that it was wrong to commit it. The burden of proof is always on the defendant, or on the person who asserts the insanity of another, to establish its existence by a preponderance of evidence. This universal rule is applicable to the issue of mental unsoundness or irresponsibility in every case in which it may possibly arise. The defendant in this case signally failed to meet the burden which the law imposed on him. It was after experts called on his behalf had related in his presence with minute detail the symptoms of "shell shock" and of epilepsy and the effect of each on the nervous organism, as manifested by the external actions of those thus affected, that the defendant, on resuming the witness stand, seemed to pass from a rational state into a state of faulty memory and finally into a state of apparent unconsciousness and collapse which cause a temporary cessation of the trial. Judgment of conviction affirmed.

Medical Bills Under Workmen's Compensation Law

(Sandberg v. Seymour Dress Co., Inc., et al. (N. Y.), 212 N. Y. Supp. 432)

The Supreme Court of New York, appellate division, third department, modifies an award of the state industrial board in favor of the claimant for compensation under the workmen's compensation law of that state, by striking therefrom five sums awarded as compensation to the claimant on account of medical bills of physicians, which amounted to $1,007. The court says that under section 13 of the workmen's compensation law, no claim for medical or surgical treatment is enforceable, except (1) as incidental to, or a part of, an award to an injured employee, and (2) unless, within twenty days following the first treatment, the physician or surgeon furnishing the treatment shall furnish to the employer and the industrial board a report of the injury and treatment on a form prescribed by the industrial board. This applies to every claim by a physician or surgeon for services rendered to an injured employee, payment of which is sought through an award by the industrial board, and whether employed by the employer or employee. This, of course, has no application to the right of a physician or surgeon to recover in an action at law from the employer for services rendered at his request.

Action for Penalty for Practicing Without License

(State Board of Medical Examiners v. Buettel (N. J.), 131 Atl. R. 89)

The Supreme Court of New Jersey, in reversing a judgment of nonsuit which was granted on the ground that the evidence did not sufficiently identify the defendant, says that the action was to recover a penalty prescribed for practicing medicine and surgery without first having obtained and filed a license issued by the state board. There was identity of names and of the person arrested; also proof that Buettel had his office at a certain place, where witnesses testified that they were treated by him, and that a pharmacist had received prescriptions from him. This, the court thinks, was sufficient to justify a finding that the defendant was the person charged and who had treated the witnesses as patients, although, while he had given bond for his appearance, he did not appear at the trial. The proper method of review was that observed, by writ of certiorari.

Nor does the court agree with the contention of the defendant that, having demanded a trial by jury and been refused, the nonsuit should be sustained on the ground that his constitutional right of trial by jury had been infringed. An examination of the authorities establishes beyond question that the right of trial by jury does not extend to actions for penalties for offenses of minor character unknown to the common law. The court thinks it apparent that the legislative right to deal in summary fashion with offenders under legislation for acts not in themselves criminal, enacted under the police power, is not doubted, but, where a jury has been accorded, it has been because the legislature in the particular case has not interdicted the right to a jury trial, but indicated the procedure to be under statutes in which the right is preserved.

The conclusion which the court reaches is that the act under which this proceeding was taken is a valid exercise of the legislative power, and that the legislature clearly intended that the proceeding should be heard in summary manner without a jury. That the steps in the proceeding are not fully set forth, the court thinks is not a ground on which to nullify that purpose. Where in the act they are left open, it will be presumed that the course of procedure in the trial court was intended. This does not render the act unconstitutional. The right of trial by jury is invoked according to the nature of the prohibited act and does not rest alone on the mode in which it is to be tried. It is the substance and not the form that must control in determining the right. The court in the present case sits solely by legislative mandate, and for the purposes of the trial is a statutory tribunal.

Annulment of Marriage for Concealment of Epilepsy

(Busch v. Gruber (N. J.), 131 Atl. R. 101)

The Court of Chancery of New Jersey, in granting petitioner Busch, otherwise called Gruber, a decree annulling her marriage to the defendant, says that the only question in this case was whether or not, if the defendant was afflicted with epilepsy at and before the time of his marriage to the petitioner, knew it, but represented to her that he did not have epilepsy, or concealed from her the fact that he had it, it was such a fraud as would entitle the petitioner to a decree annulling the marriage under the general equity jurisdiction of this court. It has been held that tuberculosis is such a cause; also syphilis. To warrant the court in granting a decree for fraud, the fraud imposed on the petitioner must be of a character affecting an essential of the marriage relation. It seems to this court that epilepsy falls within this doctrine as certainly as do syphilis and tuberculosis. The false representation in the case at bar consisted of the defendant's statement that he was in good health and had never been sick since he was a child and had had no occasion for a physician when, in fact, he was, and for a considerable period of time had been, an epileptic. He suppressed the truth, even if he did not make an affirmative false representation as to the particular fact of epilepsy, and the fraud for which a marriage will be annulled may be either a false suggestion or a suppression of the truth. In other words, this court is clearly of the opinion that, when a man who contracts marriage is and has been suffering from epilepsy but represents to his prospective wife that he is in good health, has never been sick, and has had no occasion for a physician, and within a short time after the marriage has epileptic fits, and his wife then for the first time discovers the disease with which he is afflicted, and straightway leaves him, having had no knowledge of his condition at or before the time of the nuptials, the wife is entitled to have the marrage annulled for fraud, notwithstanding consummation.

Death from Inhaling Carbon Monoxide Accidental Injury

(Cantor v. Elsmere Garage et al. (N. Y.), 212 N. Y. Supp. 327)

The Supreme Court of New York, appellate division, third department, says that when a physician went to a garage at 8 p. m. to get his car he saw and talked with a workman, who appeared perfectly well; nor did the physician notice any smell of gas in the garage. Shortly afterward the workman helped another to move into position, while its engine was running, a car that came in, and then he went to the door to admit another car. Soon after that it was said that he "looked funny." He fell down and made a noise two or three times, when breathing. When a physician was about to be summoned, the one mentioned above returned, at about 9 p. m. He found the man dying. There was a strong odor of gas in the garage; the doors were closed. The physician stated that in his opinion the cause of death was carbon monoxide gas. It thus appeared that the man did not suffer from a gradual and continuous inhalation, but the infliction was quick and of short duration. He suffered an accidental injury, which arose out of the employment. The accident was the inhaling of the carbon monoxide gas, which in itself is odorless, and which had been quickly disseminated in the garage shortly before the man fell to the floor, perhaps while he was helping to push into place the car, the engine of which was running. The presence of the gas was unexpected, and, while the breathing was voluntary, the breathing of a poison gas was not voluntary. If one drinks a glass of water, apparently clear and pure, it is a voluntary act; if, however, unknown to him, this water contains a not distinguishable poison, drinking the poison is not to him voluntary, but an accident. The time when the accident occurred was fixed. It seems that there was present here every element of accident, no niches vacant, and the direct resultant injury was poison and death. The award to the widow and minor children of the workman of compensation under the workmen's compensation law should be affirmed.

Penalty Not Excessive for Illegal Sale of Morphine

(Smith v. State (Okla.), 240 Pac. R. 656)

The Criminal Court of Appeals of Oklahoma, in affirming a judgment of conviction of an illegal sale by defendant Smith of one capsule of morphine for the price of $1, says that the trial court fixed the penalty at a fine of $500 and imprisonment in the state penitentiary for five years. It was urged that the penalty assessed was excessive. But it may have developed in evidence that the defendant was an old offender. The illegal sale of narcotic drugs is a most reprehensible practice, having a debasing influence on both the seller and the buyer and on society in general, and meriting severe punishment. The penalty here assessed was not the maximum prescribed by the statute. Under such circumstances there was no showing made which would warrant this court in modifying the sentence imposed by the trial court. The court will take judicial notice that morphine is a "narcotic drug" within the definition of that term as contained in section 8886 of the Compiled Oklahoma Statutes of 1921. It is not necessary to negative the exceptions or provisos contained in the narcotic drug act in any complaint, information or indictment laid under the act.

Medical Facts and Judicial Precedents—Tuberculosis

(Fraze v. McClelland Co, et al. (Iowa), 205 N. W. R. 737)

The Supreme Court of Iowa, in affirming a judgment which allowed the plaintiff compensation, says that, while he was assisting in moving a large and heavy oak door, the door tipped and squeezed him against the wall. That was the accident. It was momentary, the door being immediately righted. He gave no cry, but immediately afterward sought a bench and lay down feeling quite sick. He later resumed his work, which he continued for three days, when he reported his condition to his foreman, who sent him to the company's physician. The physician found a small red spot on the plaintiff's chest; also, unsatisfactory internal conditions in the chest. The final development was pulmonary tuberculosis. The plaintiff had weighed from 165 to 170 pounds up to the time of his injury, but after it rapidly lost weight until he was reduced to 135 pounds. It was contended that no causal connection between the alleged injury and the tuberculosis had been shown. Two very distinguished medical specialists in tuberculosis testified hypothetically that tuberculosis results from infection and never from traumatism. They, however, did not deny, but impliedly admitted, that tuberculosis might be accelerated and "lighted up" by traumatic causes, though they also testified that the injury to the plaintiff, as described in the hypothetic question, was not adequate to such acceleration or "lighting up." The decisive turn of the case was at this point. The industrial commissioner cited decisions from the courts of last resort of three states, wherein it was found that acceleration of pulmonary tuberculosis had resulted from traumatic causes. This court is not disposed to establish or to contradict medical facts by judicial precedents. Whatever the medical facts may be, as proved in a particular case, they must control regardless of judicial precedent. In the case at bar, this court regards the evidence as close on the question of causal effect, but it thinks also that the evidence of the plaintiff was sufficiently preponderant to sustain the allowing of compensation.

Society Proceedings

COMING MEETINGS

American Laryngological Association, Montreal, Canada, June 3-5. Dr. George M Coates, 1811 Spruce Street, Philadelphia, Secretary.

American Laryngological, Rhinological, and Otological Society, Montreal, Canada, May 31-June 2. Dr. Robert L. Loughran, 145 West 58th Street, New York, Secretary.

American Neurological Association, Atlantic City, June 1-3. Dr. Henry A. Riley, 870 Madison Avenue, New York, Secretary.

American Ophthalmological Society, Hot Springs, Va., June 14-16. Dr Emory Hill, Professional Building, Richmond, Va., Secretary.

American Orthopsychiatric Association, New York City, June 5-6. Dr. Karl A. Menninger, Mulvane Building, Topeka, Kansas, Secretary.

American Otological Society, Montreal, Canada, May 31-June 3. Dr. Harold Walker, 390 Commonwealth Avenue, Boston, Secretary.

American Pediatric Society, Niagara Falls, Canada, May 31-June 2. Dr. Howard Childs Carpenter, 1805 Spruce Street, Philadelphia, Secretary

American Psychiatric Association, New York City, June 8-11. Dr. Earl D Bond, 4401 Market Street, Philadelphia, Secretary.

American Psychopathological Association, New York City, June 11. Dr. Sanger Brown II, 173 East 70th Street, New York City, Secretary.

American Therapeutic Society, Philadelphia, June 10-12. Dr. W. J. Mallory, 1720 Connecticut Ave., N. W., Washington, D. C, Secretary.

Associated Anesthetists of the United States and Canada, Nottingham, England, July 20-23 Dr. F. H. McMechan, Avon Lake, Ohio, Sec'y.

Maine Medical Association, Poland Springs, June 10-12. Dr. B. L. Bryant, 265 Hammond Street, Bangor, Secretary.

Massachusetts Medical Society, Springfield, June 8-9. Dr. W. L. Burrage, 182 Walnut Street, Brookline, Secretary.

Medical Library Association, Ann Arbor, Mich., June 8-9. Miss Harriet Wilson, 535 North Dearborn Street, Chicago, Secretary.

Montana, Medical Association of, Billings, July 16-17. Dr. E. G. Balsam, 222 Hart Albin Building, Billings, Secretary.

National Association for the Study of Epilepsy, New York City, June 7-8. Dr. A. L. Shaw, 108B The Albiston, Utica, N. Y, Secretary.

New Jersey, Medical Society of, Atlantic City, June 17-19. Dr. J. B. Morrison, 97 Halsey Street, Newark, Secretary.

North Carolina, Medical Society of the State of, Wrightsville Beach, June 15-17. Dr L. B. McBrayer, Southern Pines, Secretary.

Oklahoma State Medical Association, Oklahoma City, June 22-24. Dr. C. A. Thompson, 609 Barnes Building, Muskogee, Secretary.

Rhode Island Medical Society, Providence, June 3. Dr. J. W. Leech, 369 Broad Street, Providence, Secretary

Wyoming State Medical Society, Lander, July 12-13. Dr. Earl Whedon, Sheridan, Secretary.

MEDICAL SOCIETY OF THE STATE OF NEW YORK

One Hundred and Twentieth Annual Meeting, held at New York March 30-April 1, 1926

(Concluded from page 1652)

Basic Factors in Human Hypersensitiveness

DRS. ROBERT A. COOKE and WILL C. SPAIN, New York: Allergy occurs in a small proportion of the population. In one such patient a 5 grain (0.3 Gm.) tablet of acetylsalicylic acid produced cyanosis, shock and death from asphyxia. Many people have no such symptoms. There exist in the blood plasma of sensitive persons substances that can be transferred to the skin of the normal person and confer a local and temporary hypersensitiveness. The patient to whom the serum has been transferred reacts as the original patient reacted. These substances are relatively stable and are present in a proportion of those suffering from clinical symptoms.

Clinical Result After the Long Continued Use of Insulin

DR. JOHN RALSTON WILLIAMS, Rochester, N. Y.: One group of patients has been studied who have been treated before and since insulin was available. Twenty-eight of these in the preinsulin period lost food tolerance, and after insulin was started twenty-seven of them gained. In the preinsulin group fifteen patients lost weight. After insulin, twenty-four patients gained weight. Before insulin, children rarely showed any growth; since insulin, children have grown rapidly and developed normally. In regard to the fate of patients, before insulin, 66 per cent lived; since insulin treatment, 85 per cent have lived In seventy-one diabetic patients, death occurred from complications in thirty-one cases. Insulin has been found effective in cases of indiscretions of diet. Patients have frequently passed into coma from dietary indiscretions and have been brought out of it by insulin, without apparent harm. One patient has had as many as 4,200 injections about the thighs without harm No increased susceptibility to other diseases has been noted in any insulin cases.

DISCUSSION

Dr Nelson G. Russell, Buffalo: Insulin has lessened the morbidity of diabetes in that it has improved the general condition of the patient, improved his resistance to operative shock, and improved his resistance to other diseases. It has been mentioned that diabetic patients age more rapidly, even with insulin, than do normal persons. In regard to the dosage of insulin, and whether we cannot improve further the general condition of the patients: Most patients have died as a general indirect result of underfeeding. Many persons keep to a lowered diet for some time, and then go on one grand spree, because they are delighted when the tests show lower sugar and that the dosage can be lowered Then they become careless. I do not think in the majority of cases that one can lower the dose Sometimes we have had to lower the dose because we have had reactions—not the regular, insulin reactions, but reactions occurring at irregular times. While we cannot come to final conclusions as to insulin for a long time yet, I think Dr Williams has made it clear by his study of twenty-eight cases that the morbidity of the disease has disappeared Putting his patients back to work was a remarkable result In regard to vascular change, I think there is a definite relation between hypoglycemia and heart muscle change I believe that definite cardiac changes can be demonstrated

The Relation of Vitamins to Disease

Dr E. V. McCollum, Baltimore: We now recognize six vitamins, A, B, C, D, E and, in addition, one which Dr Goldberger has named P P (pellagra preventive). Vitamin A is contained in animal fat. When it is lacking in the diet xerophthalmia, or drying of the whole conjunctival sac, exists. Bishop and Evans have found that there is ovarian disturbance. The female rat has reduced ovulation, and there is also a purulent secretion in the nasal and oral cavities. In regard to vitamin B, we are very uncertain what is the result of vitamin deficiency, but there is a profound disturbance of the peripheral nervous system. Recent evidence seems to point to the fact that there are two or more substances in vitamin B. This vitamin is found in yeast, and Goldberger thinks that yeast will cure pellagra in man and a similar disease called "black tongue" in dogs. Goldberger has made dilute alcohol extract of cornmeal, supplemented by autoclaved yeast which contains a substance indispensable for growth, but which alone does not prove to be an antineuritic substance. The pellagra preventive substance appears to be in the yeast. Vitamin C prevents scurvy, and also widespread hemorrhages in the tissues. This substance is most frequently found in the liver oil of fishes, chiefly of cod. Vitamin D deficiency is found when the diet is deficient in calcium and in phosphorus. In rickets, the blood content of phosphorus is very low; the calcium may or may not be low. If it is below 10 mg. per hundred cubic centimeters of blood, it means rickets with tetanus. Infants born in the late summer have to go through the winter with heavy clothes, deprived of much of the sun's rays, and therefore should have cod liver oil as a routine. Light of certain wave length seems to produce the same physiologic effects as does cod liver oil. The blood cholesterol is affected by ultraviolet radiation, and inert cholesterol is converted into a form physiologically active by ultraviolet rays. The antirachitic value of any substance is due to this form of cholesterol. Vitamin D is contained in an oil found in the wheat germ. Wheat germ oil does not prevent or cure rickets or other vitamin deficiency disease, but it does cure sterility in animals. Deprived of this substance, which is plentiful in cereals and in muscle tissue of animals, the rat cannot carry its young to term. This fact cannot be applied to human beings because of the widespread distribution of this substance. In the animal, lack of it produces emotion, nervousness, abnormal fear, lack of or loss of hair, tendency to destroy the young, and failure to produce milk. Probably the most important vitamin deficiency in this country is the deficiency of calcium in diet. Therefore diet should be considered in respect not only to vitamin content but also to biologic value of the proteins, and in regard to its mineral content. We must also remember the profound importance of other qualities that go to make up a satisfactory diet.

Vitamin Value of Some Common Foodstuffs

Dr. Walter H. Eddy, New York: People are interested in vitamins, proteins and carbohydrates. A housekeeper wants to know when she goes to market just what is contriubted to nutrition by carrots, beef or potatoes. Where are we going to get the vitamins that have been spoken of? We must have some quantitative assay method to measure these foods. The vitamin problem is something that has come along in the last decade. As new vitamins are discovered, all our previous measurements as to the value of a foodstuff are faulty. We have to discard them and start again in the light of new facts. Thus, we have found that bananas hold an antiscorbutic value; from 10 to 15 Gm. of bananas will protect against scurvy, but what else will it do? The diet must be complete in all known factors. We have to study the comparative value of ripe and of unripe bananas. We have found that bananas baked in their skins are even more effective than without Oxidation tends to destroy vitamins; therefore vegetables, canned when fresh and sealed at once, have their vitamins preserved more than vegetables cooked on the stove, as the latter lose vitamins through oxidation. Vegetables put in the can go on breathing after being canned, so that after thirteen hours there is no oxygen in the can. They are taken out of the can oxygen-free. Thus, food protected from oxidation keeps its vitamin content. Apples in storage tend to lose vitamin C content, which is lost by oxidation. If steeped in 2 per cent salt solution they are better protected. This does not, however apply to peaches, which do not have an oxygen-carrying substance. Spinach is a vegetable which has a rich vitamin B content.

DISCUSSION

Dr. George Dow Scott, New York: I was very much interested in what Dr. Eddy said about bananas. I think there is a great deal of misunderstanding in regard to the fruit, whether ripe or unripe. I have stated that a child can digest better the banana ripened on the tree, where the starch is transformed into fructose, than the banana ripened en route. The digestibility of the fruit is altered. In children having trouble with dentition I use corn meal for its carbohydrate and energy content, and I order vegetables given with the water in which they are boiled. In cases of gastrointestinal intoxication I have given raw carrot juice or turnip juice with great advantage. The teeth came more promptly and the gums improved in condition. I believe that the American diet for children has too low an inorganic salt content. By adding calcium and phosphorus, one can balance the metabolism better.

Fatigue During Work Carried on at a Regulated Rate of Speed.—Otto Graf of Munich (*Ztschr. f. d. ges Neurol u Psychiat* **101**:115, 1926) has found that work at a regulated speed is less fatiguing than work at volitional speed. As an instance of regulated speed, he mentions Ford's automobile factories, in which each worker's materials are moved up to and past him at a given speed, and his work must be carried out during the interval at his disposal. He ascribes this somewhat surprising outcome of his experiments to the fact that work at regulated speed necessarily allows for and enforces a large number of regular, though brief, periods of rest The sense of monotony also is less at the regulated speed, because the attention is not allowed to flag, and the mental fatigue of constantly refocusing the attention is avoided Graf warns against premature attempts to apply the findings of these preliminary studies generally in industry.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in America for a period of three days No foreign journals are available prior to 1921, nor domestic prior to 1924. Periodicals published by the American Medical Association are not available for lending, but may be supplied on order. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested).

Titles marked with an asterisk (*) are abstracted below.

American Journal of Anatomy, Philadelphia

37: 1-179 (March 15) 1926

Polynuclear Ova and Polyovular Follicles in Opossum and Other Mammals: Problem of Fecundity. C. G. Hartman, Austin, Texas —p 1.
Renal Circulation: Finer Distribution. D M. Morison, San Francisco. —p 53.
Jugular Lymph Sac in Albino Mouse. G. M Higgins, Rochester, Minn. —p 95.
Relative Viability of *Male and Female* Mouse Embryos. E. C. MacDowell and E. M. Lord, Cold Spring Harbor, N. Y.—p. 127.
Studies in Hyperthyroidism. II. Significance of Changes in Thymus Glands of Thyroid Treated Tadpoles C. C. Speidel, University, Va. —p 141.
***Development* of Hypophysis Cerebri in Man: Pars Tuberalis. W. J. Atwell, Buffalo.—p. 159.

Development of Hypophysis Cerebri.—Atwell's studies lead him to suggest that it seems not unlikely that certain of the tumors described by Erdheim as arising from "rests" of the craniopharyngeal duct are in fact tumors of the pars tuberalis.

Hookworm in Ceylon: High Incidence with Moderate Degree of Infestation. J. F. Docherty, New York —p. 160

Cause of Death in Anaphylaxis.—The cause of death in *true anaphylaxis*, Redfern feels, is primarily due to contraction of the smooth musculature of the body. From his studies it seems that in primary antiserum toxicity the rapidly increased permeability of endothelial linings and cell membranes is the most significant factor. The hemorrhagic and edematous condition exhibited by the lungs, the hemorrhagic local areas in the skin, and the failure of smooth muscle to contract in vitro all substantiate this belief.

American Journal of Public Health, Albany, N. Y.

*Value and Safety of Simplified Method of Pneumo Encephalomyelography. F. Liberson, New York —p 231
Traumatic Coxa Vara W. Colin, New York.—p 242

Results of Radiotherapy of Cancer of Tongue.—Primary cancer of the tongue has been healed by Schreiner and Brown with radiotherapy in sixteen out of forty-six cases in which the disease was localized for periods varying *in time up to* four years and one month. In cases showing metastases only palliation was effected. In eleven out of seventy-seven patients with metastases, the primary lesion healed; six recurred on the tongue in from two months to one year after, and the remaining five remained healed at the time of death, which was caused by metastases in the neck.

Pneumo-Encephalomyelography.—A method of simultaneous displacement of the cerebrospinal fluid by air is *described by* Liberson with illustration of mechanism and technic, and its use is emphasized in cord cases, and cases other than brain tumors. The safety of the method is compared with other methods, by citing the immediate and remote after-effects as observed in forty cases.

American Journal of Tropical Medicine, Baltimore

6: 115 166 (March) 1926

*Cure of Clonorchiasis by Tartar Emetic A C Reed and H. A. Wyckoff, San Francisco —p 115
*Amebic Colitis Transduodenal Medication. A. F. R. Andresen, New York —p 119
*Tertiary Lesions of Frambesia Tropica, or Yaws. L. H. Bittner, Buitenzorg, Java —p 123
*Experimental Rat Bite Fever. M Theiler, Boston —p 131.
*Significance of Cholesterol in Tropical Hydrocele H. M. Stenhouse, St Croix, V. I.—p 143
Occurrence of Anopheles Vestitipennis in Porto Rico H A. Johnson. —p 153

Pseudospirochetes of Leptospira. H. Vervoort, Medan, Sumatra —p. 165.

Tartar Emetic in Clonorchiasis.—In the case reported by Reed and Wyckoff, in the final series of thirty-four intravenous injections a total of 2 3 Gm. (35 grains) of tartar emetic was given in a period of five months. In addition to and preceding this series, the patient received *four* intramuscular injections of tartar emetic totaling 0 26 Gm and three intravenous injections of 1 per cent solution, totaling

0.1 Gm. No dangerous reactions were encountered. At no time did the urine show renal irritation. The first stool negative for clonorchis ova was after the fourteenth injection. After the eighteenth injection, one egg only was recovered, viz., after the twenty-third injection.

Amebic Colitis.—In amebic dysentery the active amebas are protected from destruction by the plugging up of the ulcers with débris. This plug, Andresen says, can be removed by the transduodenal enema. Powdered ipecac, given through the tube immediately after the ulcers are cleaned out, can get in its effect where most needed. Emetine, given hypodermically, may be a useful adjuvant.

Tertiary Lesions of Frambesia Tropica.—Bittner contends that rhinopharyngitis mutilans, keratoma plantare sulcatum, and juxta-articular nodules are all tertiary lesions of frambesia tropica or "yaws." Neo-arsphenamine is almost a specific in treatment of these cases.

Experimental Rat-Bite Fever.—A spirochete closely resembling *Spirochaeta morsus-muris* was demonstrated by Theiler in the blood of guinea-pigs and white mice injected with the blood taken from a typical human case of rat-bite fever. White mice and rats are readily infected with the spirochete. These animals show no symptoms but harbor the organism in the blood for a long time. Guinea-pigs inoculated with the spirochete, after an incubation period of from six to fifteen days, develop fever, enlargement of the lymph glands, inflammation and later induration of the external genitals and loss of hair. Rabbits were infected by subcutaneous, intradermal, and intratesticular injection of blood containing the spirochetes. About half of the animals used developed no symptoms, but their blood was infective for guinea-pigs for three weeks after inoculation. In the serum of infected rabbits, strong spirocheticidal properties are developed.

Significance of Cholesterol in Lymph Stasis.—Stenhouse is of the opinion that cholesterol has something to do with the production of lesions associated with, characterized by or resulting from an obstruction of lymph channels, and that it is the cholesterol that causes the obstruction.

Archives of Dermatology and Syphilology, Chicago

13: 465-600 (April) 1926

*Use of Mercurochrome-220 Soluble in Treatment of Infectious Diseases of Skin. H. H. Young, J. H. Hill and W. L. Denny, Baltimore.—p. 465.
Lichen Planus Erythematosus. C. D. Freeman, St. Paul.—p. 489.
*Syphilitic Alopecia: Relation to Neurosyphilis. U. J. Wile and G. H. Belote, Ann Arbor, Mich.—p. 495.
*Blood Cholesterol Findings in Syphilis and Other Skin Diseases. I. Rosen and F. Krasnow, New York.—p. 506.
*New Application for Varicose Ulcers. R. H. Davis, St. Louis.—p. 519.
Mycosis Fungoides and Kindred Conditions. W. J. Highman, New York.—p. 522.

Mercurochrome in Treatment of Infectious Diseases of Skin.—Of twenty-four patients with erysipelas treated by Young, Hill and Denny, twenty were cured or greatly improved; of eleven patients with furuncles and carbuncles, ten were cured and one greatly improved; of four cases of chancroidal ulcerations, all healed rapidly; of thirty-six patients with cellulitis and abscesses, twenty-one recovered promptly with no other treatment, and nine showed marked improvement and recovery after mercurochrome therapy, other treatment also being given; in two cases of gas gangrene, the infection was eliminated; in one patient with diabetic gangrene, an accompanying infection was checked; three patients with pemphigus showed marked improvement, two of them so far without relapse; of four patients with psoriasis, two are apparently cured, one markedly improved, and one improved, but with a relapse; one patient with eczema is temporarily improved; in one case of syphilis with exterior skin lesions, the lesions were healed; of forty-four patients with leprosy, twenty-eight were improved, with remarkable disappearance of the skin ulcers.

Syphilitic Alopecia.—Wile and Belote assert that syphilitic alopecia of the essential type has a high associated incidence of meningeal syphilis, as indicated by spinal fluid findings. Microscopic study shows that the essential syphilitic alopecia is not due to any local pathologic disturbance of the scalp, or more specifically, of the follicular apparatus. It is therefore not a true syphilid. Clinical analogy affords the suggestion that it is due to endocrine dysfunction, as a result of association and involvement of the autonomic nervous system. Symptomatic alopecia representing a smaller group of the entire syndrome is a true syphilid, apparently caused by a perifollicular plasmoma.

Blood Cholesterol in Syphilis.—The blood cholesterol was found by Rosen and Krasnow to be low in 100 per cent of patients with untreated primary syphilis, 50 per cent of the secondary cases in which treatment was not done, and in 25 per cent of the untreated tertiary cases in which treatment was not done. After treatment all primary cases showed a rise in the cholesterol content to normal or above normal, whereas in some of the secondary and tertiary cases the content remained low. The cholesterol content in 60 per cent of pregnant syphilitic women showed a high cholesterol value, 35 per cent a normal value and 5 per cent a low value. The blood cholesterol content in two infants with active manifestations of syphilis was low. The blood cholesterol content in 82 per cent of the treated patients who had congenital syphilis was normal. There seems to be no direct connection, at least as far as these studies are concerned, between the cholesterol content of the blood and the results of the Wassermann reaction. The cholesterol content of the blood was high in psoriasis and dermatitis venenata and normal in acne vulgaris, dermatophytosis and dermatitis seborrheica.

Treatment of Varicose Ulcers.—Very encouraging results are reported by Davis from the use of a solution containing 63 Gm. of boracic acid and 28 Gm. of solid potassium hydroxide to 200 cc. of water in the treatment of varicose and traumatic ulcers.

Archives of Neurology and Psychiatry, Chicago

15: 407-536 (April) 1926

*Pathology of Paralysis Agitans. C. M. Byrnes, Baltimore.—p. 407.
Sensory Disturbances in Tumors of Cervical Spinal Cord. F. Tilney and C. A. Elsberg, New York.—p. 414.
*Gross Pontile Bleeding in Traumatic and Nontraumatic Cerebral Lesions. G. Wilson and N. W. Winkelman, Philadelphia.—p. 455.
*Correction of Colloidal Gold Solutions as Applied to Lange Reaction. N. Novick, New York.—p. 471.
Delayed Posttraumatic Intracranial Compression. A. O. Wilensky, New York.—p. 475.

Pathology of Paralysis Agitans.—Byrnes examined the muscular tissue obtained by biopsy from fourteen cases of paralysis agitans and from one case of the postencephalitic parkinsonian syndrome. In the paralysis agitans cases he found a lesion of the neuromuscular bundle which has not been described previously in this or in any other disease. It is characterized by edema, early degeneration of the intrafusal nerve and final disintegration of the entire spindle. The intramuscular nerve trunks are normal, and the surrounding musculature is, as a rule, unaltered. The lesion in the neuromuscular bundle is, therefore, essentially neuropathic and involves a specific system of proprioceptive nerve terminals. Although studied in a variety of diseases, no lesion similar to that observed in paralysis agitans has been discovered in the neuromuscular bundle. There is reason to believe that the lesion is a toxic parenchymatous degeneration of the intrafusal nerve terminals. The cause of the lesion is not known.

Pontile Hemorrhage in Cerebral Lesions.—Wilson and Winkelman report thirteen cases, each of which presented pontile hemorrhage, usually multiple; in addition, every brain showed an extrapontile lesion. Of the thirteen cases, five were traumatic, four vascular, three neoplastic and one an abscess. This series of cases of bleeding into the pons is taken from 129 necropsies, of which twenty-six were traumatic, forty vascular, fifty-two tumors and eleven abscesses, making the incidence about 10 per cent.

Titration of Colloidal Gold Solution.—A method of titration of a good colloidal gold solution, a 1 per cent sodium chloride solution to the extent of 1.7 cc. as an indicator being used, is suggested by Novick. This salt is an electrolyte and a precipitant of colloidal solutions, and serves as an accurate and highly satisfactory indicator of the reaction state of a prepared colloidal gold solution.

Anesthetic Gases.—Brown and Henderson point out that the methane series will probably not yield an anesthetic gas. Propylene appears a better anesthetic than ethylene, the percentage required being slightly more than half that needed with ethylene. Owing to the large amount of oxygen that can be supplied there is evidence that the metabolic effects of anesthesia are decreased to a minimum with propylene.

Emetic Action of Strophanthidin.—When kombé and *hispidus strophanthin*, and cymarin are hydrolyzed, a cleavage product, strophanthidin (or strophanthigenin), is produced. This substance retains the pharmacodynamic properties of the original glucosides in a general way, but it differs from them in that it is more easily eliminated, or somehow made inactive. Of the various effects which it can produce, the emetic action is very prominent. The emetic action has been studied especially by Dresbach and Waddell, and particularly with reference to the heart as its possible seat. It is concluded that, as the emetic action persists consistently in cats with denervated hearts, the seat of action is not in the heart, or at least not entirely in that organ. Evidence is presented in opposition to the idea that strophanthidin emesis is reflex, and the opinion is offered that it is entirely central. The bearing of this conclusion on the explanation of the emetic action of digitalis bodies in general is pointed out.

Acute Aniline Poisoning.—Experimental production of acute and chronic aniline toxemia failed to produce methemoglobin as shown by spectroscopic and chemical analysis. In the acute stage of aniline intoxication, there is a relative increase in erythrocytes, hemoglobin and oxygen capacity, with a very low blood pressure simulating a condition of shock. Chronic aniline poisoning produces an anemia with the accompanying symptoms, as emaciation and weakness. The brownish discoloration of the blood and urine is due to the presence of paraminophenol, which is held in the blood plasma and which does not influence the oxygen capacity of the blood. Hence, Young says, in aniline poisoning (especially in the acute stage) cardiac and not respiratory treatment is indicated.

Acetanilid Poisoning.—Young and Wilson assert that the action of acetanilid on the heart, blood and circulation is essentially the same as that of aniline. Acetanilid, like aniline, forms paraminophenol in the blood plasma and urine. This may account in part for the cyanosis observed in acetanilid poisoning. Prolonged administration of sublethal doses of acetanilid produces anemia and emaciation. The fall in the red cell count, hemoglobin and oxygen capacity is parallel. The first toxic action on the heart appears to be a change *in the conduction mechanism.* The *type of change* and amount depends on the rate of injection as well as the amount of drug given. Acetanilid in aqueous solution in amounts sufficient to produce the cardiac changes described do not influence the respiration to any appreciable extent.

Epidural Anesthesia for Perineal Prostatectomy.—Extradural injections of various quantities of methylene blue solution were made by Shaw in eleven fresh cadavers in an effort to determine the upward extension of solutions injected through the sacral hiatus. It was found that from 15 to 20 cc. completely filled the extradural space in the sacral canal and that solution in excess of this quantity extended into the thoracic and lumbar regions of the vertebral canal. In 100 cases of perineal prostatectomy, extradural nerve block anesthesia was effected. There was 17 per cent failures to anesthetize completely. Best results were obtained with from 15 to 20 cc. of 3 per cent solution of procaine. The blood pressure was found to be the best indicator of the patient's condition. The systolic blood pressure frequently fell from 30 to 50 mm. without any change in the patient's appearance. Practically no reaction occurred in the patients receiving from 15 to 20 cc. of 3 per cent procaine. The ultimate mortality was 3 per cent. None of the deaths were attributable to anesthesia. In Shaw's opinion, the supplementation of extradural block with transsacral injection is unnecessary.

Pyelovenous Back Flow.—Hinman and Vecki assert that the content of a closed hydronephrosis is neither cumulative nor stagnant, but undergoes a continuous change, fresh material being secreted by the kidney and the excess removed by an active reabsorption, which occurs mainly through pyelovenous back flow.

Fibrous Partition in Bladder Causes Obstruction.—Wallace reports a case in which the cause of the obstruction was a fibrous partition or diaphragm extending from a point one-half inch (13 mm.) to the left of the internal sphincter forward to a point just behind the left ureteral orifice, whence it passed along the interureteric ridge, stopped just short of the right ureteral orifice, and had an attachment at a point one-eighth inch (3 mm.) from the right internal sphincter. It was a firm thin membrane about 1 inch (2.5 cm.) high and not more than one-twentieth inch (1 mm.) in thickness. It constituted a distinct diaphragm or septum, which divided the bladder into two portions, each one of which was capable of holding a considerable amount of urine. Under the influence of straining, this fibrous band was drawn downward toward the internal sphincter, so that it practically occluded the urethral orifice, and thus prevented normal emptying of the bladder.

Urinary Antisepsis.—Davis discusses the drugs with laboratory findings such as to indicate a theoretical clinical value and which will cause the secretion of the antiseptic urine by normal human individuals. Chlor-mercury fluorescein has not as yet received a thorough clinical trial. Acriflavine is of distinct clinical value in acute urinary infections, but gives results in chronic infections that are inconstant and not permanent. Furthermore, chemically pure acriflavine is obtained with difficulty, and gastro-intestinal symptoms are not infrequent. Mercurochrome-220 soluble seems to have given good results in some cases, but is not dependable. Besides, there are severe reactions associated with the intravenous administration of mercurochrome. It is excreted in the urine only in small percentage. Mercurochrome is of definite and proved value in the form of local instillations into the bladder or posterior urethra. Hexylresorcinol is of splendid experimental promise, but awaits clinical confirmation. Promiscuous medication with so-called urinary antiseptics without painstaking investigation to eliminate mechanical or systemic causes of infection is distinctly contraindicated.

Hexylresorcinol in Urinary Tract Infections in Women.—The clinical evidence reported by Wynne is said to support the claim that hexylresorcinol exerts a distinct antiseptic action in the urine of patients suffering from urinary tract infections whether due to coccal or bacillary infections. This action is apparently sufficient to disinfect completely the urinary tract in some cases.

Occurrence of Froin Syndrome.—The syndrome of xanthochromia and massive coagulation, or the Froin syndrome, consists of a yellow spinal fluid which coagulates spontaneously on standing. Kamman observed the syndrome of xanthochromia and massive coagulation (*a*) above and below tumors of the spinal cord, (*b*) in diffuse syphilitic lesions of the central nervous system, and (*c*) in a case of cord compression by an extradural abscess.

Pulmonary Embolism.—In the presence of known thrombosis, or when an unexplained slight postoperative fever suggests the possibility of hidden thrombosis, Herrmann says the development of embolism should be kept in mind. The distinctive feature in each of seven cases reported, which should suggest the diagnosis of embolism, was the very abrupt onset. Initial symptoms are: sudden anxiety and restlessness, with dyspnea, tachycardia, precordial oppression, persistent belching, and a shocklike state with rapid soft pulse, cold extremities, and profuse perspiration. In the course of several hours there follow pleuritic pain, fever, bloody sputum, and the appearance of a dull area in the chest, especially over the right lower lobe, with distant or absent breath sounds, and often a friction rub. The bronchial breathing and râles of pneumonic consolidation are lacking. Cyanosis is extreme in massive embolism.

Causes of Death in Diabetes.—Whereas 75 per cent of deaths in cases of diabetes before the advent of insulin were caused by coma, today the greater number of deaths are due to cardiovascular diseases. As a result, many cases can be prevented or postponed by the proper education of the patient. The responsibility of the doctor rests in the early detection of typical symptoms and laboratory findings of acidosis.

Stoffel Operation for Spastic Paralysis.—Lebreton and Cleary have operated on seventeen patients with spastic paralysis. Five were hemiplegias and the remainder mostly paraplegias. In eight cases the internal popliteal nerve was attacked; in five, the obturator; in three the median, and in one the sciatic nerve. There were no infections. One boy died soon after operation, the cause of death being acute tonsillitis, endocarditis and general septicemia. The necropsy showed clean wounds over the obturator nerves. Excluding this one case, there remained sixteen cases, of which one half could be classified as good results. Four showed only fair results, and four poor results.

Treatment of Scarlet Fever.—The thirty-four cases reported by Bly are divided into three groups: Twelve patients received convalescent whole blood, with a mortality of 25 per cent. Of these, eight were in desperate condition. Two of the fatal cases showed hemolytic streptococci in the blood culture, while acute nephritis caused the third death. Ten patients received convalescent blood serum; all recovered. Twelve patients received Dochez' serum; all recovered. Dochez serum appeared to bring about a more rapid improvement in the symptoms of the toxemia, and, particularly, an earlier disappearance of the exanthem. Every patient was kept in bed at least twenty-one days, counting from the first day of illness. In the absence of renal involvement, the drinking of generous amounts of water was urged. Frequent washing of the lower bowel with physiologic sodium chloride solution is done. When the angina is severe, the necessary amount of water may be introduced in this way. Believing that attention to the throat and nasopharynx decreases the incidence of middle ear involvement, Bly very gently flushes out the nasopharynx, and then the fauces are painted with a 20 per cent solution of mild silver protein All this is done six or eight times in the twenty-four hours. In 1,133 patients with scarlet fever treated at the Rochester Municipal Hospital, otitis media occurred in 7.95 per cent. Nephritis was a complication in 1.63 per cent of the cases.

Nonspecific Protein Therapy of Carbuncles and Syphilids.—In Weirauk's opinion, milk injections constitute the method of choice for treating carbuncles. The favorable effect, if such is forthcoming, manifests itself promptly, and such an effect will be secured in a majority of cases If there is no improvement after two or, at a maximum, four days, the case can be handled surgically. The same conclusions are justified with reference to cases of furunculosis. Syphilitic skin lesions show marked improvement or even complete regression following a course of milk injections. The latter, also, appear to be productive of good results in the management of old syphilitic patients who have been victims of overtreatment to their own physical detriment.

Ascaris Nephritis.—The view that ascarides secrete toxic substances that are absorbed by the host, Africa and Guazon assert, should be given thoughtful consideration, as they may be a factor in the production of serious lesions of obscure causation found not infrequently in remote organs accompanying heavy *Ascaris* infestation. This may afford a better explanation of the toxic symptoms of ascariasis than the mere theory of "reflex action."

Serology of Lepers' Serums.—Ninety-two lepers were examined serologically by Schobl and Ramirez with the view to deciding certain doubtful points in the serology of leprosy. Slight individual differences were found to exist in lepers' serums and in normal human serums alike as to content of natural hemolysins and complement, but no distinct quantitative differences were found between the serums of lepers and those of normal persons. The amount of hemolytic complement in the lepers' serums was found to be the same as that in the serum of nonlepers and is subject to individual variations.

*Reactions Following Use of Quinidine B Gordon, Philadelphia —p 49
Fifty Cases of Pyelitis in Children. R. M. Lord, Providence.—p 51.

Serious Reactions Following Use of Quinidine.—Gordon reviews some experimental work done to determine the cause of sudden or unexpected deaths following quinidine administration As a result of these experiments, it was found that quinidine has a peripheral depressant effect on the respiratory apparatus of cats, which proves fatal at a time when the heart, though somewhat intoxicated, is still viable. Stimulation of the respiratory mechanism by caffeine, combined with artificial breathing, provides a satisfactory means of preventing such fatalities. There is positive evidence of heart muscle intoxication and vasodilator effect following the use of the drug However, the respiratory paralysis cannot be explained in any other way than as a specific effect on the respiration and not as the indirect result of the low blood pressure. Successful methods of resuscitation substantiate this view. Experience in the clinic with one patient, who died following quinidine therapy and who showed respiratory embarrassment some hours before death, makes it seem likely that the means of resuscitation resorted to in these experiments might be used in human cases. It is suggested that artificial respiration be employed with caffeine intravenously in doses comparable to the amount used in the animal experiments (about 0.5 Gm intravenously for the average adult).

Acute Hemorrhagic Pancreatitis with Epigastric Hernia. D. S. Fairweather.—p. 654.

Effect of Exercise on Insulin Action in Diabetes.—Lawrence found that the immediate effect of exercise in increasing the fall of sugar caused by insulin is very great. This occurs only during the maximum period of insulin activity—that is, from one to four hours after injection. Severe and prolonged exercise, and half the usual dose of insulin, may produce as great a fall of blood sugar as the usual dose without exercise. Besides the immediate fall of blood sugar, exercise causes insulin to burn more carbohydrate than usual and to deplete the body stores of carbohydrate. For this reason the dose of insulin succeeding exercise has often an unusually powerful effect in producing hypoglycemia. If the diet is kept constant, an increase of exercise over days and weeks allows a reduction of insulin to be made. This is one of the reasons why the dose of insulin can often be reduced early in treatment when patients leave the hospital and adopt a more active existence. If this reduction is not made, symptoms of hypoglycemia appear. When the added exercise is omitted, the insulin must be raised again.

Kastle-Meyer Test for Detection of Blood.—From experiments with this test applied medicolegally by Glaister, it would appear that it is very delicate and reliable in the detection of hemoglobin. It is apparently a worthy substitute for Day's test. With the Kastle-Meyer test there are no "borderline" results. The reaction is well marked, is practically immediate, and time is economized in not having to await soakage of the stains before applying the test, if the watch-glass method is utilized. The age of the stain does not apparently affect the delicacy of the test. The test should be used in conjunction with the microscopic examination of stains for the detection of the presence of mammalian blood corpuscles and the precipitin or serologic test in determining the source of the blood, provided the examiner has by experience of the latter test acquired sufficient knowledge to determine in an accurate manner the results obtained.

Maldevelopment of Esophagus.—In the case cited by Theron, the esophagus ended abruptly with a slight dilatation just above the level of the bifurcation of the trachea, having no connection with the latter at that point. At the same level, in the middle line posteriorly, a narrow tube, with a lumen of about 1 mm., opened from the trachea and gradually widened until it joined the cardiac end of the stomach. The stomach and duodenum were normal.

Suppurating Gonococcal Epididymitis.—Among 1,982 cases of gonorrhea, Ingram found only three cases of suppurating gonococcal epididymitis.

Carbon Monoxide Poisoning.—Two cases of carbon monoxide poisoning are recorded by Hunter in which the source of the gas was a small open grate fire.

Adams-Stokes Disease with Syncopal Attacks.—A case of Adams-Stokes disease is reported by Levine and Matton in which attacks of syncope lasting from several seconds to about five minutes occurred. During the very long attacks epinephrine chloride was injected directly into the heart and was followed by prompt recovery. In one of these and for a period of five minutes, no heart beat could be seen, heard or felt. It is suggested that under such circumstances the customary beneficial effects from epinephrine, if given subcutaneously, would not be obtained, as the circulation is then at a standstill. In one of the major attacks, from which the patient recovered, ventricular fibrillation, lasting three and a half minutes and followed by complete inactivity of the ventricles for seventy-nine seconds, was displayed.

Veratrum Viride in Auricular Fibrillation.—Wedd and Drury summarize their clinical and experimental observations as follows: Alcoholic solutions of veratrum viride, when given to patients suffering from auricular fibrillation, produce slowing of both the auricular and ventricular rates of beating and a fall in blood pressure. These circulatory changes are independent of general toxic effects. Veratrum viride has, in addition to the vagal action already observed, a direct action, similar to quinidine, on the auricular muscle of the dog. This direct action will, on the circus movement theory of auricular fibrillation, tend to slow, and the vagal stimulation tend to enhance, the rate of the auricular oscillations. The relative preponderance of these two actions will determine the resultant auricular rate when the drug is administered to patients suffering from auricular fibrillation. The slowing of the ventricular rate by veratrum given orally occurs much earlier than that following digitalis bodies. However, as a therapeutic agent, veratrum is somewhat handicapped by uncertainty and irregularity of action. It may be useful in cases in which simultaneous slowing of ventricular rate and lowering of blood pressure is desired.

Etiology of Aortic Regurgitation.—An examination made by Harmer of 467 patients with aortic valvular disease disclosed these facts: Syphilis is an important factor in the production of aortic reurgitation; 37.3 per cent of all patients with aortic regurgitation between 20 and 70 show a positive Wassermann reaction. Rheumatism is of rather less importance and accounts for 27.2 per cent of the cases. Pure aortic regurgitation is mainly a disease of middle life, from 40 to 50, while combined aortic regurgitation and mitral stenosis is essentially a disease of young people, under 30 years of age. Fifty per cent of all cases of pure aortic regurgitation are syphilitic in origin, and 17.4 per cent rheumatic. Between the ages of 20 and 35, 44 per cent of cases of pure aortic regurgitation are rheumatic in origin and 10.7 per cent are syphilitic. From 35 to 40, 14.3 per cent of cases are rheumatic and 40.5 per cent syphilitic, while over 40 years of age, only 5.2 per cent of cases are rheumatic and 71.3 per cent syphilitic. Syphilis is of most importance as an etiologic factor in patients over 35 years of age, because syphilitic aortitis, and hence aortic regurgitation, is not pronounced enough to cause cardiovascular symptoms until from twenty to twenty-five years have elapsed from the infection. Rheumatism is of most importance as an etiologic factor in patients under 35, because rheumatic fever is essentially a disease of young people and cardiovascular symptoms due to rheumatism appear on the average 11.6 years after the attack of rheumatic fever. Syphilis and rheumatism are both of lesser importance in the causation of aortic stenosis (with regurgitation), syphilis accounting for only 20 per cent and rheumatism for only 13.4 per cent of the cases.

Treatment of Ankylostomiasis by Glycerin.—Twenty-two patients with ankylostomiasis have been treated with glycerin by Shelley on the theory that as the mature parasite usually occupies a portion of the duodenum or the proximal part of the jejunum, if the glycerin could be given in such an amount as to form a pool around the parasite, it would dehydrate it, and by so doing kill it. The method of administration is as follows: The patient remains one day in bed on a liquid diet. One ounce (30 Gm.) of magnesium sulphate solution is administered in the evening. Next morning, from 3 to 5 drachms (11 to 18 cc.) of glycerin is given. One ounce of magnesium sulphate solution is administered the same evening. The advantages of this method are said to be that it is entirely free from danger and it rapidly relieves the abdominal pain.

Disintegration Products of Radium Used for Skin Diseases.—The application of the later disintegration products of radium to the treatment of certain skin conditions is discussed by McHutchison and Brown. The radio elements, radium D and radium E, have been extracted from used radium emanation tubes, and in equilibrium together have been prepared for medical use in the form of applicators of different kinds. Such applicators have been found to exert a beneficial action in the treatment of lupus erythematosus, and of various types of nevi. The radiation from radium D and radium E has the unique property, so far as radium treatment of skin conditions is concerned, that it is all absorbed by the part being treated, since its effective penetration is only about 3 mm. of tissue. Radium D and E applicators retain their strength and may be used for many years; sixteen years elapse before the activity declines to one half of its original value.

Blood in Pulmonary Tuberculosis.—The blood in 100 cases of far advanced pulmonary tuberculosis in adults was examined by Tanaka. The leukocytes were always increased in number, on an average of about one fifth of the normal value, while the erythrocytes were always diminished about one fifth. The hemoglobin percentage was diminished about one fourth of the normal. In women, the count was lower than in males. There was no great difference of the color index in normal adults, or in incipient, moderately advanced and far advanced cases of pulmonary tuberculosis. The differential leukocyte count was approximately normal, except that the large mononuclears always showed an increase of about 35 per cent. Mast cells were also increased about two or three times above normal. "Shift to the left" of the Arneth count was observed not only in far advanced cases, but also in moderately advanced and occasionally in the incipient cases. The degree of dislocation to the left corresponded with the degree of advancement of the tuberculous process. On the other hand, if this count tends to assume a more right handed dislocation with a decrease of large mononuclears and mast cells, the prognosis becomes more favorable and indicates the improved result of the treatment.

Dysentery Anatoxin.—Dumas, Ramon and Bilal injected seven volunteers subcutaneously with 0.5 cc. of dysentery *anatoxin. A slight inflammation with* edema appeared at the point of injection, from two to four days later. It persisted for two or three days, and was not accompanied by any general reaction. A second injection (1 cc. of anatoxin) was given after eight days. Then 0.2 cc. of serum from the blood, withdrawn three weeks later, neutralized from one to four lethal doses of dysentery toxin in rabbits. Heating seemed to reduce notably the antigen property of the vaccine. The blood serum from the vaccinated did not agglutinate the Shiga bacillus or other dysentery bacilli. Thirty-one marines on a vessel on which there had been a small epidemic of dysentery on the last cruise were inoculated with the anatoxin before sailing. The ship physician reported that he did not note any morbid phenomena, except slight local reactions. Further observations will establish whether injections of the dysentery anatoxin are able to confer immunity during an epidemic, also the duration of this immunity.

Tuberculosis of Lung Lobules. D. Jaquerod.—p. 58.
Tuberculous Tracheobronchial Glands in Children. Mikulowski.—p. 67.

Abscess of the Spleen of Typhoid Origin.—In Morel, Dambrin and Tapie's case, a woman, aged 27, developed an abscess of the spleen, at the end of typhoid fever. The diagnosis wavered between suppuration of the spleen and pleurisy, until the roentgen rays revealed an abscess below the diaphragm. The left half of the diaphragm was pushed up and was immovable. There was no effusion in the pleura. The spleen was incised, and the patient recovered completely. Typhoid bacilli were found in the pus cultures. Forty-three of fifty-seven cases, cited by Grand-Moursel, ended by death; no surgical intervention had been attempted. Of thirteen cases treated by operation, a fatal issue occurred only in one. The spleen had been removed in this case. Incision of the spleen by way of the pleura and diaphragm seems to be the operation of choice for abscess of the spleen.

Scleroderma on the Fingers.—The history of Poussepp and Rives' patient was as follows: A girl with glandular tuberculosis and manifestations of sympathetic hypertonus, such as exophthalmos, inversion of the oculocardiac reflex and dilatation of the pupils, developed, at the age of 8, atrophy of the phalanges with joint lesions. The process spread to the skin, accompanied by depigmentation, dilatation of the veins and local warmth. Histologic examination showed the characteristic lesions of scleroderma. The latter occupied the domain of the cephalic vein, like a band passing from the dorsal part of the wrist to the forearm, and ending on the upper arm. Abnormal conditions in the sympathetic nervous system may have been responsible for the scleroderma. It seems theoretically plausible that these changes may have been induced by the tuberculous virus, to which the sympathetic system is peculiarly sensitive.

*Pandy Test in Syphilis. A. Starobinsky and H. Kaufmann.—p. 192.

Pandy Reaction in Syphilis.—The Pandy test for globulin in the cerebrospinal fluid appears valuable at the onset of neurosyphilis, when the Wassermann reaction may be still negative. Starobinsky and Kaufmann recommend this test as simple, rapid and sensitive. One drop of cerebrospinal fluid is added to 1 cc. of a 7 per cent phenol solution. The reaction is positive if there is a cloudy precipitate. Of 273 tests, the Pandy test harmonized with the Wassermann in 233; in thirty-two it seemed to be more sensitive; in eight it was negative while the Wassermann test was positive. The response to the Pandy test was most intense and constant in general paresis; it was always negative in chronic nervous affections of nonsyphilitic origin. It can be applied by any physician; even at the bedside.

*Aleukemic Myelosis. S. Goia.—p. 167.

Artificial Pneumopericardium for Pericarditis with Effusion.—Yacoel and Giroux report a case of tuberculous pericarditis with effusion in a man, aged 45. Puncture releasing 350 cc. of fluid did not prevent the reappearance of the effusion in a few days. Then 600 cc. of fluid was removed, the tapping this time followed by injection of 300 cc. of nitrogen. The relief was immediate. The puncture with injection of nitrogen was repeated a month later. The patient soon improved so far as to be able to take a walk daily, without discomfort. The punctures were continued every two months, for a year, till the man died from tuberculous peritonitis. It is possible that the fatal outcome might be postponed much later, if the insufflation of the gas was made at the onset of the affection. The punctures were made in the left fifth intercostal space, 5 cm. from the sternum, using the lumbar puncture needle. The method did not cause pain or marked shock. The procedure might prove a powerful adjuvant in rheumatic or serofibrinous pericarditis; and improve recurring tuberculous pericarditis or pericarditis associated with nephritis. Artificial pneumopericardium should be preferred to pericardiotomy, which does not prevent the formation of pericardiac adhesions. The latter is indicated only in acute purulent pericarditis and tuberculous abscess of the pericardium.

Transformation of Aleukemic into Leukemic Myelosis.—Goia's patient presented marked enlargement of the liver and spleen, with blood of the aleukemic myelosis type. Grave anemia with the characteristic blood findings of leukemia developed by the end of the year. The leukocyte count increased to 60,000; there was also a large number of young marrow-cells. Aleukemic myelosis may be easily mistaken for Banti's disease. The error is fatal if splenectomy is performed. Goia suggests that injection of epinephrine might serve, as well as puncture of the spleen or trephining the tibia, to mobilize the myeloblasts, myelocytes and lymphoblasts in the blood, from stimulation of the hematopoietic apparatus. Differentiation from pernicious anemia can be based on the hyperchromemia with the latter. The clinical picture of an advanced internal cancer, with bone metastases, may be identical with that of aleukemic myelosis. Only careful roentgenography may avert the mistake. Aleukemic myelosis, not pseudoleukemia, is the proper term for the disease.

*Blood Cholesterol and Blood Pressure. G. Richard and J. Roesch.—p. 363.
Advantages of Chloramine for Sterilization of Drinking Water. E. Techoueyres and Pillement.—p. 366.

Results of Prolonged Insulin Treatment in Diabetes.—Of Labbé's twenty-four diabetic patients treated with insulin for two or three years, 50 per cent have died. Five died in coma, but they had neglected the dietetic restrictions, or the treatment had been inadequate or begun too late. This occurred mostly in the summer when the patients were not under close surveillance. Three patients died from an intercurrent infection with suppuration; four from tuberculosis of the lung. Labbé emphasizes that while tuberculosis complicates diabetes more frequently in France than in America, death from pneumonia in diabetes is, on the contrary, rarer in France. He concludes that prolonged insulin treatment is unable to check the progress of the morbid process; it only retards it. The action of insulin does not consist in regeneration of Langerhans' islands, but in stimulation of pancreas functioning. Recuperation of the functioning may in time, in certain cases, lead to retrogression of the diabetes, but no cure has been reported as yet.

Blood Cholesterol in Hypertension.—Richard and Roesch found no parallelism between the degree of arterial hypertension and the amount of blood cholesterol in eighty persons with high blood pressure. On the other hand, there was no connection between the content of urea and of cholesterol in the blood, although hypercholesteremia was frequently present in Bright's disease. A considerable azotemia may be accompanied by only slight hypercholesteremia. All their patients with chronic and severe headache presented a notable cholesteremia, with azotemia and blood pressure rather low.

Genatropine in Digestive Pathology. Surmont and Polonovski.—p. 370.
*Chordoma in an Infant. R. Argaud and A. Lestrade.—p. 375.

Chordoma in Sacrococcygeal Region.—Argaud and Lestrade say that their patient is the youngest in whom this kind of tumor has ever been observed. The girl, 14 months old, was examined for abdominal disturbances suggesting intestinal obstruction. The liver appeared enlarged, with metastatic nodules on the anterior surface. The discovery in the pelvis of a tumor, the size of an infant's head, in front of the sacrum, explained the liver metastases and phenomena of obstruction. A minute incision back of the anus allowed the escape of a bloody gelatinous fluid, containing elements confirming the diagnosis of a chordoma. No trauma had occurred in this case. Some bone lesion, possibly of osteomalacia nature; might have been the causal factor.

*Anaphylactic Syndrome in Measles After a Burn. S. Progulski and F. Redlich.—p. 359.

Disturbed Glucose Regulation in Pregnancy.—Labbé and Chevki's research included fifty-three pregnant women. Glycosuria was found, fasting, in 5.8 per cent; the glycemia appeared normal in all. Glucose tolerance tests were followed by a rapid rise in the sugar content of the blood, the increase persisting longer than usual. Glycosuria was manifest in 27.7 per cent. The alimentary hyperglycemia in pregnancy may be due to disturbed glucose regulation, associated or not with exaggerated permeability of the kidneys for glucose. This seemed to be connected with insufficiency of the liver. The disturbance of glucose regulation was transient; but it reappeared in successive pregnancies, gradually becoming more pronounced. Thus it is possible that pregnancies may sometimes be responsible for the origin of diabetes.

The Helminth Fauna in a Bird.—Skrjabin found in a wild duck 251 specimens of helminths, belonging to seventeen different species. He knows of no other instance in which so many helminth species were found in one host.

Action of Ultraviolet Rays on Carbohydrates.—In Bierry's experiments, the action of ultraviolet rays on carbohydrates was analogous to that of a soluble ferment. The production of gases resembled that induced by yeasts. Thus may be produced an actual ultraviolet fermentation.

Increase of Sulphur After Removal of Suprarenals.—Loeper, Decourt and Tonnet removed one suprarenal gland in dogs. This was followed by an increase of the sulphur in the blood, and by changed oxidation ratio. This fact explains the increase of sulphur in melanoderma. The suprarenals, normally, probably retain the sulphur.

Anaphylaxis Syndrome in Measles After a Burn.—Progulski and Redlich treated a 4 year old child for second degree burns on the face and body. A similar accident had occurred a year before. The general condition was good, and the healing of the burns was progressing rapidly, when suddenly fever with rhinitis and conjunctivitis appeared the eleventh day; Koplik's spots the next day, and a typical measles eruption a day later. At the same time urticaria developed, similar to that in serum sickness; it vanished in an hour, but reappeared the next day. The child had recovered by the seventeenth day. Evidently this was a case of an anaphylactic syndrome, accompanying measles in a subject sensitized by the waste products in the burned skin. The measles eruption was the unleashing factor. The fixation of the measles antigen in the skin may release products similar to those from burns. Or there may be a certain kinship between the measles antigen and the waste products of organ tissues.

*Diagnosis of Triplet Pregnancy. S. Genell.—p. 41.
Hysterectomy After Expulsion of Mole. Lévy-Solal and Dupont.—p. 46.

Grafting of Ovary Tissue.—Pettinari applied ovary grafting in 332 animals, dogs, rabbits, rats, etc. The grafts survived only in animals of the same species and with a manifest deficiency of the sex hormone. The results were negative in cases of old ovariectomy, or after removal of the uterus. An early grafting seemed to prevent the by-effects of ovariectomy. It also stimulated the mental activity and functioning of different organs in old animals. The experimental findings afford a sound basis for ovary grafting in women. The clinical indications for it are: defective or arrested development of the sex organs; removal of ovaries and pathologic menopause; sterility of ovarian origin; syndromes from endocrine glands, also certain mental affections. Further research may prove the efficiency of ovarian grafts in senility. The purpose of the grafting may be stimulation of the ovarian gland or substitution of its function. The grafts may be implanted in the genital organs or close to them, intraperitoneally or extraperitoneally. Good results were obtained with implants in Douglas' pouch or in front of the bladder. It is possible that the retrorenal space may be advantageously used for implantation of the ovary.

Triplet Pregnancy Diagnosed by Roentgen Ray.—Genell reports a case in which palpation, abdominal and rectal, as well as auscultation of the fetal heart sounds suggested the diagnosis of a twin pregnancy. Roentgenograms revealed the presence of three fetuses. The two infants first born presented a common placenta and chorion; while the third had its own placenta and membranes. The woman died ten hours later from eclampsia without convulsions, and secondary anemia.

Axial Torsion of Uterus with Fibroma. E. Hitzanidés.—p. 103.
*Blood Coagulation and Phlebitis. E. Chauvin et al.—p. 123.
*Remote Results of Low Cesarean Section. M. Wetterwald.—p. 131.

Blood Coagulation in Postoperative Phlebitis.—Chauvin, Esmenard and Jaur compared the blood coagulation time in twenty-five persons before and after operations. An insignificant increase was noted in most of the cases after the intervention. Gynecologic operations, although these are the ones most frequently followed by phlebitis, did not seem to influence the coagulability of the blood more than any minor surgical trauma. Neither was it more affected by general than by local anesthesia. The blood coagulation time in eight patients with phlebitis showed a constant but only slight acceleration. Thus postoperative thrombosis does not appear to be connected with blood coagulation; evidently other factors share in its mechanism.

Obstetric Future of Women After Low Transperitoneal Cesarean Section.—Wetterwald states that 45 per cent of 100 women became pregnant after a low transperitoneal cesarean section. In thirteen cases the operation was repeated; the old scar in the cervix was almost invisible. In forty deliveries, childbirth occurred by the natural route. There was rupture of the scar in one of a total of forty-five women. In 62 per cent of the cases delivery was spontaneous, while spontaneous delivery after symphyseotomy has been recorded in about 59 per cent, and after pubiotomy, in 22.7 per cent. After high cesarean section, rupture in successive deliveries occurred in 25 per cent; after cervical section, in 3 per cent. Low cesarean section is also recommended for placenta praevia; ten deliveries occurred by the vagina in eight women that had been previously treated in this way. The literature records ten ruptures in the cicatrix in 3,600 cesarean sections by this technic (0.28 per cent).

Roentgen-Ray Diagnosis of Bone Tumors. P. Moulonguet and R. Lifschitz.—p. 113.
*By-Effects of Ramisection. R. Leriche and R. Fontaine.—p. 143.

Phenomena Following Ramisection.—Leriche and Fontaine report that only slight and transient disturbances followed severing the last cervical and the first dorsal rami communicantes in their fourteen cases. Postoperative pains were noted in 14.3 per cent; in one case in the temporomaxillary joint and lower teeth; in another in the acromion. They were slight and disappeared in a few days. Pain in the frontal and occipital regions occurred in three instances, in the form of mild periodic headache. Other sensory disturbances were rare. Muscular atrophy developed in one woman in the shoulder and hand after ramisection for angina pectoris; it was associated with tactile hyperesthesia. There was in all cases a slight and transient hyperemia of the nasal, laryngeal and pharyngeal mucosa, entailing brief rhinitis, hoarseness and slight difficulty in swallowing. The operation was sometimes followed by vasodilatation of the salivary glands. After cervical sympathectomy, pains occurred in 23.5 per cent of their seventeen cases; they were intense and persisting. Frontal headache was noted in one, but in no instance were there sensory changes or muscle atrophy, although all presented slight laryngeal and pharyngeal disturbances. The postoperative changes appear as a direct result from severing certain nervous fibers, or as an indirect result from circulation changes after the operation. The pains and muscular atrophy are the direct consequences; headache, sensory, laryngeal and pharyngeal disturbances, the indirect.

*Unification of Roentgen-Ray Dosage. A. Béclère.—p. 125.

Roentgen Ray in Treatment of Papillomas of the Larynx.—Solomon and Blondeau treated successfully multiple papillomas in the larynx of a young man. The growths, which had existed for nine years, caused hoarseness, then aphonia and dyspnea. Local interventions, even tracheotomy, were of little help. The roentgen-ray treatment had been started with a dose of 1,000 R. units, applied twice a week, to the right and left fields in the neck. After the third exposure, the tracheal cannula could be removed. After the seventh and last exposure the voice became normal. Reexamination of the patient, about eight months later, showed disappearance of the papillomas, which before the treatment had covered the whole of the vocal cords. The tracheal fistula healed; the young man was able to talk and even sing. A durable recovery was also obtained in two similar cases with 8,000 R. units applied in the course of twelve weeks.

Unification of Roentgen-Ray Units.—International standardization of the roentgen-ray unit is necessary for the future progress of roentgenography. This is emphasized by Béclère, who suggests the appointment of an international committee of roentgenotherapeutists and physicians for this purpose. A uniform roentgen-ray unit will make it possible, he says, to reproduce exactly in France a roentgen-ray treatment suggested, for instance, in America or England.

Latent Pulmonary Syphilis. M. Letulle and J. Dalsace.—p. 385.
*Intraspinal Anesthesia and Uremia. Abadie et al.—p. 387.
*Large Tumors in the Thigh. C. Perret.—p. 389.
Mental Anorexia of Adolescents and Adults. M. Nathan.—p. 390.
Medical Aviation in Peace Times. Julliot.—p. 395.

Anesthesia and the Blood Urea.—Abadie, Baldous and Dornier examined the blood of twenty-six persons operated on under intraspinal anesthesia. The urea content of the blood appeared always increased for about a week. It may be due partly to the surgical trauma, since different toxalbumins and nucleins are released from the injured tissues. This explains why azotemia is often more pronounced after major than after minor operations. Affections of the liver and kidneys, as well as old age may also be responsible for the high blood urea after an operation. On the other hand, the degree of the azotemia depends to a certain extent on the anesthetic used. It was considerably higher, for instance, with stovaine than with procaine. It is probable that the drugs act first on the sympathetic system, while the kidneys are involved secondarily. This does not interfere with the advantages of the intraspinal method, if the choice of anesthetics is made carefully.

Improved Technic for Operation on Large Tumor of the Thigh.—Perret describes the method he applied for disarticulation at the hip joint in two cases of enormous sarcoma of the thigh. The purpose is to avert embolism of neoplasm cells and to reduce the loss of blood during the intervention. The patient is kept in the Trendelenburg position during the whole operation. Through a small median subumbilical incision two ligatures, 1.5 cm. apart, are applied distad on the common iliac artery; then the incision is sutured. Then an incision is made in Scarpa's triangle, and the femoral artery and vein are severed, between two ligatures. This second incision is used for disarticulation of the hip joint. Owing to the slanting position, the blood contained in the tumor and limb flows back into the body. The effect is similar to that from autotransfusion. The general condition improved even before the exarticulation was completed. The color of the face looked more natural while the pulse became stronger and respiration deeper. The procedure may be indicated in case of grave traumatic wounds.

*Diabetes Insipidus from Tuber Cinereum. J. Sabrazès.—p. 12.
Hypertrophy of the Breast. E. Frommel.—p. 24.
*Pathogenesis of Psoriasis. R. Carillon.—p. 32.

Diabetes Insipidus and Tuber Cinereum.—Sabrazès reports a case of diabetes insipidus in a boy, aged 15. A brief cerebrospinal meningitis, accompanying measles, at the age of 7, probably injured the tuber cinereum, and intercurrent influenza, of a nervous form, at the age of 14, seems to have awakened the latent process in the tuber cinereum, inducing phenomena of diabetes insipidus. Subcutaneous injections of pituitary extract (posterior lobe) reduced the amount of urine from 6 or 7 liters to 1.5 liter, and greatly improved the general condition. The effect of an injection persisted only for twenty-four hours; hence the injection (1 cc.) had to be repeated daily. Intensive treatment for syphilis should always be tried, since syphilis appears to be a frequent factor in the pathogenesis of diabetes insipidus. Roentgen-ray treatment may also be tried, as suggested by Towne's favorable experience.

The Sympathetic-Endocrine Basis of Psoriasis.—Carillon ascribes psoriasis to changes in the sympathetic tonus. This deranges the metabolism of the epidermis cells, and the horny layer of the skin does not develop normally. In these conditions, the slightest irritation, of traumatic or infectious origin, is able to cause desquamation; namely, the appearance of psoriasis. Epinephrine, pilocarpine, eserine and atropine, among others, may favorably modify the sympathetic tonus. If there are signs pointing to a certain endocrine gland, then a corresponding extract can be used. Otherwise, thymus extract or insulin are indicated.

Suffocating Capillary Bronchitis. M. Roch and E. Frommel.—p. 111.

Traumatic Uronephrosis.—Cornioley thinks that uronephrosis is the proper name for what is generally called hydronephrosis. He describes the case of a man in whom the sequence of hematonephrosis, sclerosis of the kidney from distention and a recent cicatrix in the kidney pelvis was revealed at the operation. A fall on the abdomen caused rupture of the pelvis along its lower border. Owing to clotting in the hematoma, the urine did not pass through the gap, thus favoring the healing. On the other hand, the clots that formed in the pelvis induced gradual obliteration of the ureter, with associated phenomena of periureteritis. It was followed by dilatation of the pelvis, and atrophy of the renal parenchyma from compression. Nephrectomy appeared as the only rational treatment since there was already compensatory hyperfunctioning of the other kidney.

Dangers from Radioactive Substances. J. P. zum Busch.—p. 278.
*Early History of Syphilis. O. Eckstein.—p. 279.

Neuroses of Aviators.—Meier-Müller, who is chief surgeon of the Swiss Aviator Corps, and has himself experienced a few crashes, deals with the sequels of such injuries. The comparatively long period of several minutes which elapses between the realization of the imminent disaster and the final crash is horrible, and an intense reaction—beginning usually after a day or two of euphoria—is only natural. The best treatment and prevention of a neurosis consists in returning the patient to his occupation as speedily as possible. He succeeded in this way even with men whose skulls had been fractured more than once. The Swiss aviators are much better off, financially and otherwise, in service, than with a disability pension. Consequently, there are no neuroses among them. He is opposed to any compensation in the traumatic "wish" neuroses.

Bacteriophage Antiserums.—Urech and Pache produced agglutinins and amboceptors for Flexner and Shiga bacilli by intravenous injections of the homologous cultures dissolved by bacteriophages. In addition to this, these serums inhibited the action of the homologous, but not of the heterologous, bacteriophage. Prolonged contact of the serum with the bacteriophage improved the results.

Early History of Syphilis.—Eckstein reviews the early history of syphilis in China. He quotes a few passages published in 1632 by Chan-sze-ching. They are quite modern in the keen clinical observation and knowledge of extragenital and congenital syphilis. Mercury was used in treatment.

*Rational Treatment of Peptic Ulcer. M. Bufalini.—p. 641.
Reenforcement of Wall of Inguinal Canal. Fusari.—p. 671.

Tuberculosis of the Kidney.—Bloch analyzes thirty-four operative cases of renal tuberculosis, including twenty women, and four bilateral cases in both men and women. The right kidney was affected in thirteen of the women. A cold abscess developed in the bed of the kidney after nephrectomy in all but ten of the total cases, even when the tuberculous lesion had been minimal. The ultimate outcome seemed to depend on the gravity of the tuberculous process in the bladder. Reflux from the bladder into the kidney left may infect the latter. Nephrectomy was done in three of the bilateral cases, with marked improvement in one patient, and another seems to be improving rapidly since the recent operation. The one patient with bilateral disease treated by nephrotomy, died three months later. It seems to be established now that nephrectomy is a comparatively mild intervention, while the results are most promising. Even with bilateral tuberculosis, removal of the least diseased kidney may give good results. It should be supplemented with local treatment of the bladder lesions.

Treatment of Gastric and Duodenal Ulcers.—Bufalini's experience and survey of the literature have demonstrated, he says, that truly radical treatment is impossible. We must be content with palliative measures, and they must damage as little as possible the anatomic and functional conditions of the organ. It is absurd and futile to suppress an organ almost completely in the attempt to cure disease in it. This is the paradoxic behavior of those who practice extensive resection.

*Treatment of Movable Kidney. G. Pieri.—p. 398.
Total Infarction of Kidney. L. Pisani.—p. 403.

Suprapubic Prostatectomy.—In Cattaneo's service, the mortality of over a thousand Freyer operations has dropped from 14.38 per cent in 1909 to 1 per cent in the last hundred cases. He tabulates the details in this last group to show the outcome according to the indications and technic, warning that prostatectomy must not be done as an emergency operation. He prefers the two-stage technic. Calcium chloride arrested postoperative hemorrhage in 50 per cent of his cases, rendering tamponing unnecessary. Local anesthesia for the epicystotomy and epidural for the prostatectomy—refraining entirely from general anesthesia—have contributed to the favorable outcome.

Movable Kidney.—Pieri makes a lengthwise incision in the capsule at each side of the posterior surface of the kidney, and detaches the capsule between the incisions to form a bridge. This bridge is lifted up like a handle, and with it the kidney is suspended from the twelfth rib, slipping the handle over the rib. The technic is illustrated as applied in seven cases.

*Heredity and Cancer. P. Mino.—p. 112.

Early Diagnosis of Cancer.—The twenty-two articles by leading clinicians in this issue of *Minerva* are addressed to the general practitioner. They describe the earliest warning signals for the different locations of malignant disease, and reiterate the importance of suspecting cancer and establishing the diagnosis at once, even with the most apparently harmless little lump or bleeding. Histologic examination of the uterus scrapings enabled Morpurgo to detect microscopic cancer in four recent cases. Micheli commends the meiostagmin test as approaching reliability closer than any other serologic test. Bobbio emphasizes the exceptionally and rapidly malignant character of cancers in and around the mouth; even the most harmless lesions had better be eradicated. Ceconi warns that incipient gastric cancer may induce merely subjective symptoms or none. Loss of appetite and even repugnance for certain foods are usually the first symptoms, but sometimes the appetite is long retained. Vomiting may be the first sign of trouble, and the vomiting does not relieve the patient. The sudden appearance of these symptoms in the midst of apparent health is significant, especially at the cancer age. The heredity should also be considered. In regard to heredity, inquiry as to uncles, aunts, cousins and consanguineous marriages may prove instructive. The physicians throughout the country are urged to collect data bearing on the question of heredity of cancer. A copy of this issue has been sent to every physician in Italy by the newly organized Cancer Research Institute at Turin, in charge of Prof. B. Pescarolo, Senator. The articles are based on personal observations compared with case histories, and they form an exceptional manual for detection of malignancies in their incipiency. The address is Minerva Medica, Casella Postale 399, Turin, Italy.

Policlinico, Rome

33: 397-431 (March 22) 1926

*Mercury and Bismuth. L. Philippson.—p. 397.
Waxed Paper in Surgery. D. Taddei.—p. 401.
Erythroleukemic Syndromes in Infants. G. Barbera.—p. 402.
History of Medicine. C. F. Zanelli.—p. 409.

Mercury and Bismuth.—Philippson sees only quantitative differences between the action of bismuth and of mercury in syphilis. The former is less toxic. Consequently, larger doses (0.2 Gm.) may be injected. The numerous preparations of bismuth—especially those which contain less of the metal—are superfluous.

33: 433-467 (March 29) 1926

*Blood Group Tests. P. Badino.—p. 433.
Broca's Aphasia. G. Scollo.—p. 437.
Reticulo-Endothelial System. G. Notarangeli.—p. 441.
Sarcoma of the Mediastinum. S. Pera.—p. 444.

Blood Group Tests.—Badino found panagglutinins in the plasma (obtained by addition of anticoagulants) and to a less degree in the serum which separated at the temperature of 16 or 37 C. The latter specimens agglutinated every blood, including the own, sometimes even at 16 C. He concludes that careful work—especially when the test cannot be made under exact thermal conditions—requires the use of test serums which separated from blood kept in the icebox for two hours. The panagglutinins are absorbed by the coagulum in this case.

*The Life Cycle of Bacteria. A. Fontes.—pp. 163 and 197.
Protozoa Observed in Brazil. C. Pinto.—p. 211.

Colloidal Metals in Relation to Immunization.—In Genesio Pacheco's extensive research on domestic and laboratory animals and in twelve clinical cases, the colloidal metals all acted in the same manner; namely, increasing the amount of agglutinins and slightly raising the temperature, but not modifying otherwise in any way the course of the infection.

The Life Cycle of Bacteria.—Fontes is convinced that there is an ultramicroscopic phase in the life cycle of bacteria which our present methods of investigation are unable to reveal. It is evident, however, that bacteria are nucleated cells, but the nucleus is dispersed. It may mobilize and condense into granulations. The granules which stain deeply with basic stains are able individually to reproduce the species. He summarizes the life cycle as: first, granular dust, then free granulations; secondly, the phase of growth, granular multiplication and cell organization, with intracellular and extracellular emission of granules; then cell division and reproduction. The third phase is the disintegration of the cell, then granular dust and granular disintegrating lysis, with free granulations and their multiplication, with cellular organization. The discovery of the bacteriophage helps to explain the bacterial mutations from endogenous principles.

*Visualization of the Gallbladder. E. Lanari.—p. 505.
The Ultraviolet Rays in Pediatrics. J. M. Macera.—p. 516.

Treatment of Diabetes Insipidus.—Waldorp reports that in two cases of diabetes insipidus no benefit was obtained from insulin treatment, supplemented or not with calcium, potassium or sodium ions. Pituitary extract promptly improved the condition. Addition of insulin did not seem to enhance its effect.

Complications of Tonsillitis.—Segura and Viton reiterate that even an apparently very mild infectious process in the tonsils may be responsible for grave disease in the kidneys or other organs. One previously healthy young woman, after a slight tonsillitis which subsided spontaneously, developed tube casts, severe hematuria and finally alarming uremia. Acute nephritis is the most common complication, appearing with the flaring up of chronic tonsillitis. There may be hemoglobinuria with the albuminuria, but there is always more or less hematuria. In one patient with albuminuria, which was declining, the albumin climbed to 8 Gm. per liter during an attack of tonsillitis. In some cases, hematuria is the only sign of kidney involvement with recurring tonsillitis. Castaigne's patient had hematuria fifteen times in five or six years, without any other symptoms from the kidneys. Segura and Viton have witnessed the subsidence and nonreturn of articular rheumatism and appendicitis after tonsillectomy.

Visualization of the Gallbladder.—Lanari gives twenty-eight roentgenograms from his hundred patients tested with sodium tetraiodophenolphthalein by the vein or mouth. The Saralegui injector proved exceptionally useful. The findings are negative or inconclusive if the cystic duct is obstructed or the liver cells not functioning properly. The findings were negative for some unexplained reason in two cases of gallstones, one of gastric ulcer and one of epigastric hernia. In two cases of chronic cholecystitis without gallstones, the kidneys were large, with outlet free, and yet the gallbladder was scarcely visible while the kidney on that side gave a positive response, the pelvis and calices looking as if an opaque substance had been injected.

Broken Bottle in Rectum Laparotomy, Recovery Curat and Lazala —p [illegible]
*Air in the Bladder C Heuser —p 214

Treatment of Anthrax in Man—Destefano and Vaccarezza analyze 414 cases of anthrax tabulating the outcome The mortality was 10 95 per cent in 192 cases in which a 5 per cent solution of peptone was injected intramuscularly once or twice a day until the general symptoms subsided It was 15 85 per cent in the eighty-two treated exclusively with antianthrax serum and 29 41 per cent in the seventeen treated exclusively with normal beef serum Omitting the cases in which death occurred within two days, these figures become respectively 9 04 per cent for the peptone, 10 38 for the antiserum, and 25 per cent for the normal beef serum The peptone parenteral protein therapy seems to be not only more effectual, but it does not induce serum sickness

Air in the Bladder—Heuser's roentgenograms explain the mechanism of death after insufflation of air into the bladder A small amount of air was injected to facilitate investigation of a bladder tumor but no air could be seen on roentgenoscopy The procedure was repeated with iodized oil, and the oil cast a good shadow, but the air was seen to have made its way into the kidney If the walls of the urinary passages had been fragile the air might have passed into the blood stream, with fatal air embolism This danger is greater than hitherto realized as the roentgenograms showing the air in the kidney are mistaken for air in the intestines—as happened in this case at first No more than 80 cc of air should ever be injected into the bladder

Formation of Bilirubin.—Melchior, Rosenthal and Licht confirm the bilirubinemia which occurs after total extirpation of the liver in dogs. They ask, however, how large is the extrahepatic formation of bilirubin when compared with the hepatic as postulated by Minkowski and Naunyn after their experiments on birds They found that extirpation of the liver in dogs prevents the development of toluylendiamine and phenylhydrazine icterus They concluded that the liver is the most important organ of bilirubin formation in mammals as well as in birds They doubt whether the reticulo-endothelial cells have any particular significance for it

Electrocardiography.—Schellong objects to needle electrodes on account of the deformation of the curve due to polarization. He prefers small copper plates applied externally

Flora of the Duodenum.—Lowenberg believes that the gastric acid is not the only cause of the relative sterility of the normal duodenum The bactericidal properties of the duodenal fluid are more important He found almost regularly an absence of this power in pernicious anemia, and frequently in inflammations of the biliary passages

Inclusions in Erythrocytes.—Mayer, Borchardt and Kikuth found in the erythrocytes of anemic splenectomized rats inclusions which stain red with the Giemsa solution Although they do not exclude the possibility of their degenerative nature, they point to a similarity with the inclusions described in Oroya fever under the name of bartonella bacilliformis.

Action of Rays on Cells.—Gassul reports his observations with roentgen irradiation of tissue cultures. Daylight is one of the possible sources of error in such experiments. Explants of spleen tissue from normal frogs did not grow so well in the plasma from irradiated frogs as similar tissue taken from irradiated frogs and cultivated in normal plasma.

Angina Pectoris and Body Structure.—Mester has never seen a floating tenth rib in any patient with angina pectoris.

Roentgen Treatment of Tuberculosis W. Landau —p 461 C'td

Unusual Metastasis of Erysipelas.—Doberauer had erysipelas of the leg seven weeks after resection of varicose veins. Six days later, hemorrhage from the bowel and grave abdominal features developed. A cecal fistula was made and the patient was recovering. The fistula was closed a month later. This provoked a recurrence of the erysipelas as well as of the abdominal disturbances, lasting for several weeks He lost 30 Kg. (40 per cent of his former weight) The abdomen was reopened but, instead of the expected abscess, only adhesions of the intestines and infiltration of the parietal peritoneum were found. Nevertheless, improvement set in immediately, and he recovered, four months after the first erysipelas.

Old Primiparas.—Jaroschka's statistics confirm Kermauner's opinion that the age of the primipara is practically irrelevant in the prognosis of labor. The percentage of complications increases with the age only because the number of infantile and hypoplastic women who conceive at last increases with the passing years.

Fatal Accident in Roentgen-Ray Laboratory.—Polgár reports another case of death of a physician who stepped on a foot contact while adjusting a wire. He believes that elimination of all the sources of danger is the most important present problem in roentgenology.

Hemagglutinins in Cancer.—Schiff comments on Weitzner's paper summarized in these columns February 6, 1926, p. 455. He attributes the latter's results to error from pseudo-agglutination which is frequent in the blood from cancer patients. Cancer patients show about the same percentages of blood groups as healthy people of the same locality.

Insulin in Diabetes.—Minkowski regards insulin provisionally as a substance which restores the faculty, lost by deficiency of the pancreas, which had enabled the individual to utilize his metabolism in a normal way as a source of energy. Its action is more pronounced in the diabetic organism because of the loss of the faculty to regulate the own insulin production Yet a "resistance" to insulin should not be construed as a proof of an extrapancreatic origin of the special glycosuria The sugar threshold may be changed by various causes A change of the susceptibility to insulin is rare. It is usually due either to an improvement or to the progress of the diabetes Infections lower the action of insulin Pus destroys it in vitro in a few minutes. Insulin should be used in diabetes with pulmonary tuberculosis except when it induces focal reactions. One of his patients in this category requires 300-400 units daily, and has taken about 25,000 units within three months. Her blood pressure increased at the same time It is not impossible that her high resistance against insulin is due to compensatory hyperproduction of epinephrine Tyramine, which paralyzes the hyperglycemia action of epinephrine, lowered her insulin requirement. Nothing similar to this could be found in other diabetes patients normally susceptible to insulin.

Roentgenology of the Urethra.—Langer and Wittkowsky describe with illustrations the technic for roentgen examination of the urethra. One of the methods used is the exposure during micturition

The Brain in Adiposogenital Dystrophy.—Kraus found chronic encephalitis of the base of the interbrain (tuber, infundibulum corpora mamillaria and substantia perforata) in a case of adiposogenital dystrophy. The pituitary was almost normal

Surgery of the Appendix.—Schonstadt attributes to the administration of castor oil many complications in appendicitis The pulse and the muscular stiffening are the most important points in estimation of the gravity of the case. Gonorrhea should be suspected in every female patient. In acute cases with gangrene, but without diffuse peritonitis, he advises to suture the peritoneum but not to tighten the sutures in the abdominal wall unless there are no signs of peritonitis after five days. He has had no death in recent years in peritonitis. He attributes this partly to luck, partly to avoiding injury to the intestines, and to good drainage through the Douglas pouch, or (in men) perineum. He describes the technic

Treatment of Sinusitis.—Sondermann draws attention to his method of treatment of catarrhal sinusitis by lowering the intranasal pressure by aspiration.

Pathology of Twins I. E Stransky —p 613.
*Treatment of Laryngeal Diphtheria. E Burghard —p. 626.

Still's Disease.—Reimold and Stoeber noted an improvement in a case of Still's disease under injections of a streptococcus viridans autovaccine.

Treatment of Laryngeal Diphtheria.—Burghard explains the details of the expectant method used by Schlossmann. If the stenosis progresses in the first twenty-four hours after injection of the antitoxin, they do not abstain from tracheotomy. It is necessary if the larynx or trachea is suddenly occluded. They always keep everything ready for a tracheotomy which may be performed in such a condition without anesthesia. Yet their main principle consists in quieting the children by giving them narcotics and yielding to every wish. An open window is always a help.

Exudative Pericarditis.—Kamenetzky and Rabinowitsch regard exaggerated movability of the heart dulness in changes of the patient's position as a sign of pericardial effusion. It is pathognomonic if the shape of the dulness or of the roentgen shadow changes at the same time.

Serum Treatment of Pneumonia.—Brand and Kochmann injected a polyvalent pneumococcus antiserum in thirty-nine infants and small children with bronchopneumonia. Four of them (10 per cent) died. Of the forty-two controls, twenty-two (52 per cent) died.

Smallpox Vaccination and Paralysis.—Plaut and Jahnel found in extensive experimental research on rabbits no relations between cowpox virus and *Spirochaeta pallida* which might serve as a basis for any hypothesis of a causal connection between smallpox vaccination and general paresis.

A Dosimeter.—Chaoul has constructed an iontodosimeter which indicates directly the dose of rays which has been applied.

Treatment of Typhoid.—Hilgermann infected rabbits intraperitoneally with 5 cc. of a virulent typhoid culture. When he injected 2 cc. of a 4 per cent solution of sodium salicylate intravenously, from two to five hours later, the animals recovered, while the controls died the next day. One of the animals treated after five hours died suddenly in convulsions. This could be prevented by a preliminary injection of a typhoid antiserum.

Tannin Test for Cancer.—Wigand claims to demonstrate proteins in extreme dilutions (many millions) by addition of fresh tannin. He uses high titers of the patient's serum as the indicator of cancer. He claims that the only errors are from false negative reactions.

Phagocytosis and the Reticulo-Endothelial System.—Zebrowski and four other pupils of Wysokowicz recall attention to the latter's article published in 1886 in the *Zeitschrift für Hygiene*. He demonstrated that micro-organisms injected into the blood stream are taken up not only by motile leukocytes, but also by the endothelial cells of the capillaries, especially in the spleen, liver and bone marrow.

Leanness and Insulin Fattening. W. Falta. Supplement, pp. 1-15.

Roentgen-Ray Treatment in Skin Diseases.—Freund emphasizes that it is as necessary to protect the deep tissues as the surroundings. It is not only superfluous, but injurious, to use hard rays on superficial skin diseases, such as psoriasis, eczema, or for depilation. He uses filters (0.5 to 3 mm. aluminum) only for depilation and for processes localized under the skin. The rays should be about 7-8 We. hard. He uses 6-7 We., without any filter, in psoriasis. Combination with other procedures—for instance, excision in lupus with irradiation of the open surface—improved the results. He is gratified with the success of roentgen treatment in favus and similar formerly extremely chronic affections. He does not mind that the articles still being published on it never mention the originator of the idea.

Therapeutic Malaria.—Donath and Heilig found remarkable differences between the changes induced by malaria and by other fever-producing agents. The amino-acids increase in the blood after injection of vaccines and proteins, but not in malaria. Contrary to this, the amino-acid content of the cerebrospinal fluid increases notably in malaria, less in relapsing fever and after typhoid vaccine, and not at all after injection of milk. They believe that a focal reaction of the central nervous system accounts for the favorable influence of malaria on general paresis.

Extraction of Needles and Hooks in Tissues. O. Susani.—p. 791.

Illumination in Operating Room.—König prefers a grey paint for the walls of the operating room, and a greenish grey color for the sheets covering the patient.

Explosion in Acetylene Anesthesia.—Oehlecker discusses the danger of explosion in acetylene-oxygen anesthesia. It seems that the presence of particles of oil—instead of the acetylene—accounted for two such explosions. It is not sufficiently widely known that oxygen alone may cause grave explosions when it blows over oil. A whole oxygen tank may explode if oil is used to lubricate the valves. Every oxygen tank should be labeled "Beware of Approaching with Fat or Oil."

Infantilism and Matrimony.—An abstract of Van de Velde's article was given on page 1592 when published elsewhere He recommends examination of every young girl, who intends to marry, for infantilism of the sex organs It is a cause of dysmenorrhea, dyspareunia, lack of sexual satisfaction, sterility, abortions and complications of labor. Moderate degrees of the condition yield to treatment. It might be advisable to notify the bridegroom and give him advice on how to behave, because of the probable frigidity, which, however, may improve later

Gonorrhea in Women.—Maier had in Opitz' clinic further good results with Damm's litmus paper test He treats gonorrhea in the female only by weak astringents (tannin in alcohol and glycerol).

Zentralblatt für innere Medizin, Leipzig

*Blood Platelets in Pernicious Anemia E Allard —p 258

47: 289 312 (March 27) 1926

The Practitioner and Abdominal Surgery. M Friedemann —p. 289

Blood Platelet Index in Pernicious Anemia.—Allard figures the index by dividing by 50 the number of platelets per thousand erythrocytes. For instance, with normal blood (250,000 platelets and 5,000,000 erythrocytes per cubic millimeter) there are 50 platelets per thousand erythrocytes Thus, the index is 1 In pernicious anemia, the index is usually low (0 2 and less) A low index is an unfavorable sign It announces an exacerbation even if the red count is comparatively high A high index with low erythrocyte count frequently precedes a remission No good remissions can be expected with less than 100,000 platelets per cubic millimeter.

Russkaia Klinika, Moscow

5: 3 182 (Jan) 1926 Partial Index

*Roentgen-Ray Treatment of Uterine Myoma A Kaplan —p 93
"Adenoma Sebaceum." I. Olesoff —p 107.

Comparative Studies of the Vegetative Nervous System.—Functional tests of the vegetative nervous system were applied by Pletneff in fifty-four subjects. He used atropine or epinephrine tests, besides determining the oculocardiac reflex, dermographism and other diagnostic symptoms. He concludes that there is no justification for classification of all persons in two groups, namely, the vagotonic and the sympathicotonic Examination of different parts of the parasympathetic and sympathetic systems revealed functional dissociation of the two systems All the drugs injected were substances foreign to the body; they cannot reveal the true functioning of the living cells of any of its organs. The reaction of the organism to the injected atropine or epinephrine depends not only on the nervous system, but also on the biologic autotonus of the cell, the latter connected with the predisposition or some external cause. Clinical reactions to atropine or epinephrine do not show the true condition of the parasympathetic or sympathetic system These reactions may be considered merely the response of the organism as a whole to the drugs

Roentgenotherapy of Benign Uterine Disease.—Kaplan reports forty-five cases of fibromyoma with metrorrhagias, treated by roentgen rays All these patients have been under observation for about two years since the treatment The rays were applied to both ovaries and to the sacrum; each field given from 6 to 12 Holzknecht units. The dose had been gradually decreased Complete arrest of menstruation occurred in 97 per cent of the cases; the tumor disappeared in 40 per cent The roentgen-ray treatment did not induce any by-effects, the general condition of the patients improved notably.

Ugeskrift for Læger, Copenhagen

88: 235 260 (March 11) 1926

Inaugural Lecture on Forensic Medicine K Sand —p 235.

*The Pulse with Intracranial Disease R Lund —p 246.
Precautions Required in Extraction of Teeth Under General Anesthesia A Gullestrup —p 250
*Male Death Rate and Alcohol in Copenhagen K A Heiberg —p 251.

The Sedimentation Test.—Bouet has been studying the variations in the speed of sedimentation in 100 patients, including thirty-five with bone and muscle disease under parenteral protein therapy. The readings are more informative as to quantity than to quality. The variations throw light on the progress of the disease up or down, showing whether the objective findings parallel the subjective, and possibly dispelling the suspicion of malingering.

The Pulse with Intracranial Disease.—Slowing of the pulse was observed in from 28 to 65 per cent of Lund's 151 cases of otogenous sepsis, brain abscess, meningitis or encephalitis It seems to be due to toxic irritation of the vagus The mortality was 81 per cent among the sixty-five cases with bradycardia, while it was only 32 per cent in the eighty-six cases in which the pulse corresponded to the temperature. The highest degree of bradycardia was noted with an abscess in the brain The unilateral localized pressure from an otogenous abscess in the brain is an important factor likewise in the bradycardia, but it is not the only factor.

Influence on the Male Death Rate of the Restrictions on the Consumption of Alcohol in Copenhagen.—Heiberg presents statistics to show that the death rate of men has always been constantly much higher than the death rate of women, but since 1917 this difference has been wiped out in the ages between 25 and 55 Instead of a difference of 36, 56 and 77 per cent higher mortality, the difference is only 16 or 11 per cent or zero These decades are the ones most strongly inclined to alcoholism, and he thinks that these changes can be explained only as the effect of the restrictions imposed since 1917 on the consumption of alcohol. The female death rate has shown no change.

Vol. 86, No. 23 Chicago, Illinois June 5, 1926

ABSORPTION FROM THE LOWER RESPIRATORY TRACT

UNDER NORMAL AND PATHOLOGIC CONDITIONS *

H. J. CORPER, M.D.
DENVER

The problem of absorption confronts the scientific investigator in practically every field of human endeavor, in the exact as well as in the practical fields, and the mass of information thus gained will eventually lead to a more intelligent understanding of the detailed mechanism of absorption, though widely differing especially in the finer points in each special field. The inadequacy of in vitro explanations alone for biologic purposes is now and again emphatically decried by some students and with some justification, so that it would seem that the final court of decision must at present still rest in tests performed under actual existing in vivo conditions. In the biologic and medical sciences, our problem resolves itself into the solution of a complicated mechanism at the basis of which lies the intricate biology of the cell, the complexities of which we are just beginning to unravel by means of controlled researches. In many respects one should not expect absorption in the lower respiratory tract to differ from that in other parts of the body, yet the anatomic structure as well as the specialized physiologic function of this part of the human economy would certainly make one hesitate in accepting all facts derived from alien studies and applying them without reservation to the respiratory organs.

Besides the specialized differences of the cells concerned in absorption in a certain part of the body, due weight must also be given the physical and chemical nature of the substance being absorbed, whether gaseous or liquid, and in the latter case whether in solution, as crystalloid or colloid, or in suspension as particulate matter. The latter, being the more easily adjusted factor for study, has probably been given greater consideration than the tissue or cellular phase. Since gaseous exchange is one of the most significant physiologic functions of the lungs, this problem has been given major consideration, as is evident from the scientific literature on the subject, and justly so; yet there remains considerable importance attached to the subject of absorption of liquids when it is considered that the cells themselves under physiologic conditions are in a liquid state and all interchange with the outside world occurs through a liquid medium, and that under pathologic conditions the changes occurring concern to a great extent those involving the liquids of the tissues.

After the discovery of the blood and lymph circulations, interest was displayed in the proportionate parts played by these in the absorption of fluids, both normal and pathologic, and the peritoneal and pleural cavities were regarded as integral parts of the lymphatic system, though the manner of absorption of contained fluid was not clear. In 1862, the announcement of von Recklinghausen[1] that there existed open channels or stomas which established communication between the peritoneal cavity and the lymphatic system afforded a ready explanation for the absorption of fluids. Almost coincident with the refutation of the existence of stomas, Starling and Tubby,[2] in 1894, as a result of a study of the resorption of dyestuffs, peptone, proteins, sugar and salt solutions, concluded that the resorption occurred primarily through the blood vessels, in which Orlow, Heidenhain (1896) and Hamburger (1895) concurred. The latter believed that isotonic solutions were absorbed by imbibition. MacCallum,[3] in 1903, was responsible for our more rational understanding of the manner of absorption of foreign granules from the pleural and peritoneal cavities by a very slow reactive process of phagocytosis, thus stressing the importance of the cell in absorption.

The route of absorption from the serous cavities is by way of the blood and lymph vessels; and although the former are at present described in complete detail and are common knowledge, the latter are just being satisfactorily studied, and a brief review of our present anatomic information seems justified. All lymphatic vessels at their termination empty into veins, and on both sides of the body where the subclavian and common jugular veins unite. All tissue fluids and lymph from the left half of the head, the neck, the left upper extremity, the left chest, the left lung, left heart, the mediastinum, the entire abdomen, diaphragm and the greater part of the liver flow into lymph vessels emptying into the thoracic duct, while those from the right half of the head and neck, right upper extremity, right chest, right lung, right heart and a part of the liver surface flow into the right lymphatic trunk. Anastomoses between the right and left chest and those of the abdomen probably exist.

The absorption of liquids is intimately associated with the absorption of substances dissolved in them as well as the state of their solution, whether crystalloid or colloid, hypertonic, isotonic or hypotonic, but

---

* From the Research Department, National Jewish Hospital.

* Chairman's address, read before the Section on Pathology and Physiology at the Seventy-Seventh Annual Session of the American Medical Association, Dallas, Texas, April, 1926.

[3] MacCallum, W. G.: *On the Mechanism* of Absorption of Granular Matter from the Peritoneum, Bull. Johns Hopkins Hosp. **14**: 105, 1903.

the immediate and direct course of the absorption of liquids as solutions of crystalloids or colloids is difficult to follow unless the contained crystalloids or colloids[4] happen to be colored, can be tested by color reactions or precipitates, or are in the form of unchangeable dyestuffs originally. Most dyestuffs are, however, susceptible to reduction or oxidation changes in the body, and therefore absorption has been studied to a great extent by utilizing very fine suspensions of stable particulate matter which can be directly followed step by step, especially under the microscope. Thus developed the concept of the endothelial leukocyte by Mallory,[5] who in 1898 described the phagocytic mononuclear cells in the lymph nodes in typhoid. Aschoff and Kiyono now include these cells in their class of reticulo-endothelium with which are now identified the mononuclear cells of the blood stream. Finally, Sabin and Cunningham,[6] by supravital methods, have again rendered the term reticulo-endothelium meaningless and conclude that the endothelial leukocyte of Mallory, the histiocyte of Aschoff and Kiyono, the macrophage of Evans and the clasmatocyte of Sabin are identical but differ in origin from the monocyte of Sabin and Cunningham derived from the reticular or mesenchymal cell, whose primitive stem-cell is also the parent cell from which the leukocytic and lymphocytic series of cells are derived. In a consideration of absorption, especially of particulate matter, the origin and destination of the cells concerned become very pertinent, and its importance in the absorption of certain crystalloids and colloids must not be casually dispensed with, especially since it is generally accepted that these must also pass through cellular protoplasm to enter the blood or lymph vascular systems for final disposition. It has been difficult even to trace accurately the course of liquid suspensions of particulate matter far beyond the site of primary injection, but a review of a few recent studies will serve to elucidate this from the standpoint of our present knowledge of the lung and pleura.

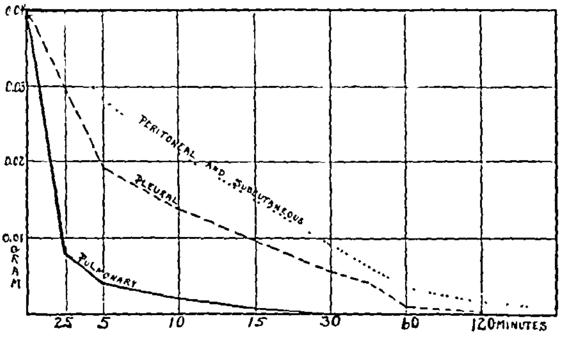

Fig. 1.—Absorption of 2 cc. of 2 per cent sodium sulphocyanate solution after intrapulmonary, intrapleural, intraperitoneal and subcutaneous injection into normal guinea-pigs. The pulmonary rate of absorption exceeds the pleural, and the latter exceeds that from the peritoneal cavity or subcutaneous tissues.

Karsner and Swanbeck,[7] in studies on cats with carmine and carbon suspensions, found that particulate matter in the pleura is taken up by endothelial cells in situ, and is transported in endothelial cells rather than as free pigment. The surface cells that participate are determined by the position of the pigment; but, other things being equal, the parietal pleura appears to be somewhat more active than the visceral pleura. The surface endothelium after phagocytosis may migrate to the underlying lymphatics, and the cells in the sinuses of lymph nodes are largely migratory cells. The phagocytic power of the cells is a primitive function existing after the death of the animal as well as during a period of spinal shock. Drainage from the parietal pleura is chiefly into mediastinal lymph nodes, whereas that from the visceral pleura is principally into the lymph nodes at the hilum of the lung. Transport from the visceral pleura is in part through the subpleural and in part through the peribronchial and perivascular lymphatics. Occasional transfer of pigment to the abdominal lymphatic apparatus was noted, but this was by no means either constant or frequent.

Lyter,[8] in experimental studies on guinea-pigs, rabbits and sheep, wished to determine the probability of particulate material (india ink) passing from the mediastinum into the substance of the lungs and the probability of its passing from the pleural surface into the lung, without concern with the question of the pathways. India ink injected into the mediastinum passed into the lung substance and into the spaces beneath the parietal pleura, while india ink injected into the right pleural cavity also passed into the lung substance on both sides as well as into the tissues of the mediastinum and beneath the parietal pleura on each side. No pigment was found beneath the diaphragmatic pleura or in the liver or spleen.

Bettman,[9] working with dogs and rabbits, found that india ink injected into a normal pleural space left an unstained visceral and parietal pleura, while the intracostal and superdiaphragmatic lymph channels were deeply pigmented, and the mediastinal and hilum glands contained large amounts of carbon. In rabbits injected with air and india ink there was a striking difference in that the carbon remained as a thin film on both the parietal and visceral pleurae, and the lymph channels and nodes were less injected.

In order to learn something of the modus operandi of the removal of an exudate from the pleural cavities, Wadsworth[10] performed experiments on dogs, cats and rabbits. India ink, milk and carmine in Ringer's solution were injected into the pleural cavity and could be traced in the parietal pleura and to a less extent in the visceral pleura, both in the living anesthetized animal and in the dead animal in which artificial respiration had been maintained for some time (from one to two hours). It is concluded by him that particulate material finds easy access to the lymphatics of the parietal pleura, and not by phagocytosis. The lymphatics of the visceral pleura were not so markedly filled as those of the parietal pleura, and here and there phagocytosis was observed. The fact that the substernal and hilum glands contained pigment even in the dead animals on which artificial respiration had been performed is presented as conclusive evidence that respiratory movements alone can act as an adequate pump for these lymphatics.

4. The terms crystalloid and colloid are used with reservation and the knowledge that when substances are introduced into the body they enter a complex physicochemical colloid system in which their true state may be altered either by physical or by chemical combination, and that, as Fischer (Handbook of Colloid Chemistry, 1915) states, "all substances can appear as colloids under appropriate conditions."

The disposition of particulate matter in the lung follows definite routes into the lymphatics converging to the hilum, which have been exhaustively worked out by Klotz, Haythorn and others in conjunction with studies on anthracosis, and hardly bear repetition here, as they are common knowledge and the literature has already been summarized.[11]
